CERTAIN remarks made by his honour Judge GREENHOW in the course of a case recently heard before him in the Leeds County Court seem to us to call for comment and protest, particularly as similar observations are from time to time made, or permitted to be made, in other courts of law. An action was brought by the wife of a labourer and the mother of a boy attending a board school against a teacher in the employment of the Leeds School Board. Her claim was for personal injuries sustained through an alleged assault, which she accused the defendant of committing upon her, her story being that when she went to remonstrate with him upon some point connected with her son's behaviour he kicked her on her thigh and pushed her down some stone steps. This somewhat improbable story was eventually not believed by the county court judge and the claim was *dismissed, not*, however, before Judge GREENHOW had made in the course of the hearing the comments to which we take exception. The plaintiff's solicitor, in order to demonstrate the fact of her injuries, proved later by the defendant to have been sustained through no fault of his, desired to call as a witness Mr. A. T. SPANTON, resident medical officer at the Public Dispensary at Leeds, who had admittedly attended her on the day in question. This gentleman declined to be sworn as a witness before he had received his fees as such, upon which the following questions and comments of his honour are reported to have ensued. "You have heard some comments on that matter and that it presses hardly upon poor people who have not several guineas to put down?" "You still persist in your intention of having the money laid down before you give evidence in this poor person's case?" "It seems to me an extraordinary line for gentlemen of the medical profession to take up that they should require the money down. They may need it in some cases, but not in all, I am sure. It seems to be a considered line of conduct on the part of the medical officers of this town to decline to give evidence without fees, and I am amazed that it should be so." We can only say that we are amazed at the surprise evinced by Judge GREENHOW. We would like to know whether he has found in his own profession of the law such a willingness to work for the poor without fees as to justify his referring to members of the medical profession in the terms we have quoted.

The medical practitioner's profession is that of medical practice. In the exercise of that profession, when patients are too poor to pay, the medical profession gives its aid ungrudgingly. In the case of the witness at the Leeds County Court Mr. SPANTON'S duties which he was engaged to perform at the dispensary involved attendance on the plaintiff. It is not part of any medical practitioner's duty, as such, to spend his valuable time in a court of law giving evidence, or waiting to give evidence, gratis It is for the solicitor who undertakes the case, and who presumably is paid for doing so, to pay his witnesses if he expects them to give evidence. If the medical witness in such a case as that on which we are commenting gives evidence on the terms upon which Mr. SPANTON was invited to do so he at once lays himself open to cross-examination and comment of a most odious and offensive character. He is in the position of a witness whose fee depends upon the success of the party on whose behalf he gives evidence, for he will only be paid if that party recovers the costs awarded to the successful litigant. Cross-examination and comment to this effect may not be permitted by all judges, but are part of the ordinary stock-in-trade of the advocate, and to some extent other cases with a slighter degree of imbecility the relation between the moral and the intellectual defect becomes much less close, and it would seem that there is not necessarily any direct proportion between them. This much, at any rate, may be stated with positiveness, that of children with slight general impairment of intellect many show a degree of moral control which would not be considered defective in a child of average intellect, whilst others whose general intellectual capacity appears to be exactly similar show a marked defect of moral control; and a child who is only slightly weak-minded may show a much greater moral deficiency than one whose weakness of intellect is much more evident.

It hardly seems necessary to quote cases in proof of these points which must be familiar to anyone who sees many imbeciles; moreover, most of the cases which I have already quoted were children who showed only minor degrees of general intellectual impairment, and I selected them purposely as having for this reason more "points of contact" with the cases which I shall consider in my subsequent lectures. I will, therefore, only add two more to those already instanced. The first case is a girl, aged five and a quarter years, of stolid appearance, although her facies does not suggest any general impairment of intellect; she is backward, did not learn to walk until the age of two years and did not talk until three years old. She does not know her alphabet but has not yet been to school, she takes an intelligent part in ordinary conversation. Her head is below the average in maximum circumference, it measures 18⅜ inches, and in the frontal region is unduly narrow. She is extremely passionate; if crossed in any way she will throw herself down on the floor and scream and kick. At meals she has on various occasions thrown cups, saucers, and knives at her mother in rage because she could not have some particular food which she desired. There are other children in the family, and when these have not allowed her to have what she wanted she has run at them and bitten them sufficiently to break the skin. She is also wantonly mischievous, turns on the water-taps and leaves them running, and has at various times stolen eatables and other things. She is said to have very little sense of obedience and corporal punishment seems to have little or no restraining effect. The second case, a boy, aged 11 years, is a pleasant-faced boy, stands up well, and as far as ordinary conversation goes might pass for a normal child. But he is decidedly backward in school attainments, can only read words of one syllable, and cannot multiply beyond twice 12; he also laughs too easily and too often. He is said to be extremely excitable and very passionate on slight provocation; he seems to take a delight in bullying other children—for example, he will go up to children who are quite strangers to him in the street and snatch away their toys, not in order to keep them, for he will give them back afterwards, but apparently because he enjoys their grief; he has stolen considerable sums of money from the teacher at school, probably twice within the last year. In both these cases the general impairment of intellect was very slight; indeed, the children could hardly be classed as "imbeciles," they were rather "backward children," but the moral defect was very marked—in fact, the latter case was sent to me for this rather than for the intellectual condition.

It would be easy to quote cases in which with a general intellectual condition as closely as possible resembling that present in these two children there was no abnormal defect of moral control; for instance, an almost exact parallel to the girl just mentioned was another girl, aged six years, with a dull appearance, who had not learnt to walk or to talk until the age of three years; she took an intelligent part in ordinary conversation but was very slow at school and could not identify the letters of the alphabet in spite of careful teaching; morally, however, this child was in marked contrast to the other, she was good-tempered, honest, and showed, in fact, no abnormal defect of moral control. It would seem, then, that moral defect in children with general impairment of intellect shows no constant proportion to the intellectual defect.

Lastly, the question must be raised whether we can associate defect of moral control with any particular type or types of idiocy or imbecility—a question of considerable importance, for if it were possible to do so we might hope by a study of these types to find some anatomical basis for this abnormality of function. Of the 23 cases to which I have referred two were syphilitic and both had had fits (in one case up to the age of seven years—that is, 18 months before I saw the boy—and i the other up to three months before [the date o observation when the boy was five years old); one wa epileptic; one was paralytic with infantile hemiplegi and fits; one was an imbecile of the Mongol type; on was a cretin who had been treated for several years wit thyroid; and of the remaining 16 who corresponde with no particular type and might be classified wit the "genetous" idiots of Dr. Ireland four had had convulsions or epileptiform attacks at some period of their life but the relation of these attacks to the intellectual impai ment was uncertain. In 16 cases the maximum circumference of the head was recorded. In six it was below th average, but only in one case (the Mongol) to any conside able degree (18½ inches at the age of five years); i two of the remaining cases it was below the averag So far, therefore, as these observations go it did not see possible to associate any particular type of idiocy c imbecility with defective moral control. The relation c moral defect to convulsions or epilepsy is, however, note worthy—the association was noted in eight out of 18 case in which the point was inquired into. This proportion i only slightly above that which has been recorded by D Fletcher Beach in discussing the causal relation of convu sions or epilepsy to idiocy or imbecility in general (namel 33 63 per cent.), quite apart from any question of mor defect, so that no great stress can be laid upon these figure I may, however, add that Dr. Ireland specially notes c epileptic idiots that "they are often wild, intractable, an irritable—in fact, seem on the boundary line between idioc and insanity"—and also says that "where epileptic attac occur eccentricities of conduct may be looked for, such a stealing, cruelty to animals, sleep-walking, or some stran outburst of temper or change of mood." As we shall se this association of morbid moral defect with epilepsy i children is not peculiar to the epileptic idiot, it is see where the general intellectual condition appears to b perfectly normal, so that we cannot attribute it to ar anatomical condition peculiar to these particular idiots; th subtler changes, whatever they may be, which produ epilepsy alone without idiocy, are equally capable of diminis ing moral control. We are, I think, driven to the conclusio that the types of idiocy or imbecility associated with defe tive moral control are too varied to allow us to connect ar particular anatomical condition with the moral defect wit out post-mortem evidence which at present is lacking. Th there are cortical changes, either in the way of arrest development—for instance, in the Mongol idiot and some of the genetous idiots—or in the form of gro lesions or degenerative changes, as in the paralytic typ seems almost certain from our knowledge of these co ditions where they have occurred without moral defec but the fact that any of these varieties of idiocy may occ without any morbid failure of moral control, and, furthe that a marked degree of such failure may occur apart fro idiocy or imbecility, strongly suggests that the cause of th moral defect is to be sought not in any gross lesion or gro failure of development but in some much finer physic abnormality, and this view, I think, will be corroborated b the facts which I shall mention in my later lectures.

If I may sum up the points upon which I would chief insist in the foregoing considerations they are these: th a morbid failure of moral control is not uncommon children with general impairment of intellect—there is, fact, a congenital limitation of the capacity for the develo ment of moral control associated with a similar limit tion of the general intellectual capacity; that exce in the lower grades of idiocy and imbecility where th cognitive relation to environment is absent or extreme defective there is not necessarily any direct proporti between the moral limitation and the general intellectu limitation; that no particular type of idiocy or imbecili can be specially associated with moral defect; nor is the any evidence, so far as can be judged from a clinical stu of these cases, that any particular gross lesion of the brain requisite to the limitation of moral control.

VACCINATION IN WORKHOUSES.—At a meetin on March 21st the Tavistock (Devon) Board of Guardia instructed the medical officer to revaccinate, at his discretio all the inmates of the workhouse above 10 years of age. The Barnstaple (Devon) Board of Guardians on March 21 decided that all tramps must be revaccinated before bei admitted to the workhouse.

they may not be altogether unfair. Is it consistent with the dignity of the medical profession to give evidence upon medical situations in such circumstances? We would put this question to a lawyer, after first inquiring whether it is considered consistent with the dignity of a barrister or a solicitor to appear for the needy litigant in similar conditions—those, that is to say, of payment dependent upon success. We seem to have heard of service being rendered under some such conditions by the firm of DODSON and FOGG, but our recollection is that the procedures of these attorneys were narrated more for our warning than as patterns of right professional conduct.

Judge GREENHOW seems to think that the medical witness should distinguish some cases from others. We doubt if it would be right or prudent that he should do so. It is for the solicitor to judge of the facts of his client's claim. If the solicitor is satisfied that he ought to do his legal work as a work of charity, let him do so by all means. Let him then endeavour, if he pleases, to convince the medical practitioner and to persuade him to do the same. But in such a case let it be charity and not a question of fees dependent upon success. In the majority of cases we are satisfied that it forms no part of the duty of a medical man to judge the merits of a litigant's claim. That is for others to do. It is the medical practitioner's duty to give evidence as to the facts within his knowledge, while he is entitled to fees for the time during which he is taken from the professional labours upon which his livelihood depends. As a rule these fees are miserably inadequate to the value of the services rendered to justice and leave him a considerable loser upon the transaction. We not only disagree with the view taken by Judge GREENHOW, but we congratulate the members of the medical profession at Leeds who, we gather from his honour's observations, have taken a firm stand in the matter and have resolved that their action shall be uniform and consistent.

Annotations.

"Ne quid nimis."

NO MEANS OF ESCAPE.

WE are sure that if a practical inquiry were set on foot as to the extent of the provision generally made in the buildings of London for protection against fire an appalling conclusion would be reached. Unfortunately, as statistics show, it is not occasionally that painful demonstrations are afforded of the utterly inadequate precautions which are thus taken. Several lives have been lost recently in London fires because there was no way of escape. London is undoubtedly swarming on all sides with death-traps only ready to claim their victims when a fire has broken out. Everyone is aware of the difficulties which have to be faced when the question of the efficient protection of life shut up in buildings in a congested area is approached. But surely no great revolution would be necessarily suggested by proposing the adoption of some step or other for securing the better protection of lives from fire. For example, in probably the majority of buildings in London it is impossible even to escape to the roof and thence to gain a safe refuge on the adjoining premises. We know at least of one instance, that of well-known bank premises, in which the boundaries of the property are marked on the roof by ugly spiked fences. While it is true that even this way of escape is not easy it is certain that in a greater number of instances no such thing as a fire ladder is available. The percentage of fires, some urge, in relation to the number of buildings in the metropolis is so very small that such a provision for a way of escape would very rarely come into requisition. But when it does how painful and appalling the outcome can be is evident from the terrible results of the non-existence of any means of escape at a fire which occurred in the city on Monday last. The example is all the more remarkable since the fire broke out in broad daylight at 5 o'clock in the afternoon and within 300 yards of the chief city fire-station. The first call, indeed, came to the brigade by a messenger on foot. In spite of the proximity of the rescue station ten lives were sacrificed in this fire because there were no means of escape and because the rescue appliances could not reach the upper floors where several poor operatives were in danger The fire-escape was too short by a few feet to reach the floor which proved a fatal cul-de-sac to several poor girls. Some of them attempted to jump into tarpaulins which, it is said, were dragged from passing carts for the purpose and held by willing hands in the street below. Several were injured in this attempt. When the fire had been got under a search revealed at least half a dozen charred bodies amongst the ruins of the half-burnt floors. On the morning after the fire one of our representatives visited the scene and he states that the building was not a remarkably high one and not so high as thousands of others in London streets. The fire brigade authorities must be aware of the length of their fire escapes and they must surely also know the extreme height of the largest buildings in the metropolis and yet in this instance the fire escape failed to reach the top floor of the building We must admit that we are not in possession of all the facts of the case, but *prima facie* there would seem to be divulged in this occurrence a distinct and serious defect in the machinery of the brigade. We trust that a searching inquiry will be made as to this failure of the rescue apparatus. Even, however, when the fire-escape is long enough to reach the roof of a building it is not always possible to seek safety by its means. We consider that no system of escape is satisfactory which trusts to the fire-ladder of the firemen. Provision should be made for exits from all floors of a building in case of outbreak of fire. If permanent fire-ladders cannot be provided some means of communication should be afforded between the building involved and the one next to it, or lifts in inclosed tubes should be constructed or openings in the roof made and a free way from one roof to another opened up We have nothing but admiration for the work of the London Fire Brigade It possesses a splendid record, but in some circumstances it is evidently powerless to save life. It can prevent in a large measure destruction to property, but it seems to us that its chances of saving life are often beyond possibility. That is no fault of the officers of the fire brigade, but is attributable rather to a glaring and hideous defect in the construction of most London premises which calls for removal wherever it exists

THE FORTHCOMING INTERNATIONAL CONGRESS OF MEDICINE.

THE Fourteenth International Congress of Medicine will be held in Madrid from April 23rd to 30th, 1903, under the patronage of their Majesties the King of Spain and the Queen Mother The President of the Congress is Professor Julián Calleja y Sánchez, the general secretary is Dr Angel Fernández-Caro, and the general treasurer is Professor José Gómez Ocaña. The chief regulations for the Congress, as at present decided upon, are as follows Members of the Congress shall be medical men, pharmacists, dentists, veterinary surgeons, and other persons working at branches of medical science, both Spaniards and foreigners, who have entered their names and paid their subscriptions. Other persons not connected specially with medicine, but who possess a scientific or professional title, may under the above conditions take part in the Congress. The amount of subscription is 30 pesetas (the official rate of exchange published in London on June 11th was 34.40), and this sum must be paid in before the opening of the Congress to the General Secretary, Faculty of Medicine, Madrid. A card of membership will then be delivered to the subscriber. Up to March 20th, 1903, the subscribers of various nationalities may pay their subscriptions to their own national committees, but after that date subscriptions must be paid directly to the general secretary at Madrid. The official languages of the Congress will be Spanish, French, English, German, and Italian Papers and other communications must be sent in to the general secretary before Jan. 1st, 1903, to be certain of having a place in the orders of the day, but communications may be made after this date, or even during the Congress itself, only they will in such case not necessarily be considered until after those which have been sent in previously to Jan. 1st have been dealt with. Papers sent in must be accompanied by a short abstract, which abstract will be printed and distributed among the members of the Congress.

SEATS AND SANITARY ACCOMMODATION FOR THE CORONATION.

Before it is too late we would urge upon all concerned the absolute necessity of providing adequate sanitary accommodation for the numerous stands where thousands of people will be "cabin'd, cribb'd, confined" during many hours on Coronation Day. In the ordinary course of nature it is obvious that at least a few of the many gathered together will feel indisposed. Some of the stands are within easy access of public lavatories, others are not. The County Council, which will dispose on its stands of some 7000 seats, is, we are pleased to hear, taking adequate measures. A number of portable earth-closets will be provided for the use of the spectators. At the War Office a special room will be set aside as a lady's lavatory, while the men will be able to reach the closets that exist for the use of the War Office clerks. Some other stands reared by private enterprise advertise that they have provided sanitary conveniences. But is this universally the case? We would strongly urge all purchasers of seats to make careful inquiries before concluding their bargains. If the public neglect this matter the speculators in seats are likely to be equally negligent and the results may be extremely distressing. Nor should the authorities be indifferent to this important question. The conditions, the circumstances, are altogether so exceptional that it is difficult to say whether there is any actual text in the law dealing with such an emergency, but in any case the spirit of the law fully meets the situation. No local authority would sanction the opening of a public assembly hall or theatre if lavatory accommodation were not provided. Yet the spectators on the Coronation Day are likely to be confined to their respective stands for a much longer period than is required to witness a theatrical performance. Therefore equally ample accommodation must be provided. Portable earth-closets are easily procured, and such high prices are paid for the seats that there is no excuse for the avoidance of this small extra expense. The borough councils are responsible for the condition of the stands in their respective districts. In conformity with, we believe, the Building Act they have to send inspectors round to see that the stands are substantially built and will not give way under the weight of the people they are destined to bear. Could not these inspectors be instructed also to make inquiries as to the sanitary accommodation provided, hinting at the same time that an indictment for creating a nuisance might ensue if the advice given were not followed. At Westminster Abbey especially we hope that proper measures will be taken, for we are informed that this was not the case at the time of the Jubilee celebration. But the matter in the main rests in the hands of the public. They will have to suffer if they do not make the necessary inquiries before they purchase seats.

THE ROYAL ARMY MEDICAL CORPS.

In a leading article that appeared in The Lancet of May 31st (p. 1546) we said that the new warrant for the Army Medical Service went a long way towards securing that state of army medical efficiency which we credited Mr. Brodrick with having earnestly had in view when undertaking to provide the army and the nation with the best medical service. At the same time we took the opportunity of recurring to a subject to which we had already frequently referred —namely, as to the position and rates of pay of medical officers whilst serving in India under the Indian Government. We were, of course, aware that this was a matter which did not come within the province of the War Office but was for the India Office to settle. It is very satisfactory to learn that the Secretary of State for India has now decided to approve of an increase to the pay of officers of the Royal Army Medical Corps below the rank of major while serving in India and also the issue of the charge allowances for senior medical officers of station hospitals there. As the increased facilities for professional study provided for in the new army medical scheme will necessitate an increase of the medical establishment we trust that Mr. Brodrick will see his way towards lessening the amount of foreign service which medical officers have had to perform as this has pressed heavily upon their service for some years past. The results of the competitive examination next month for the army medical service under the new conditions are awaited with much interest and curiosity.

CANCER IN INDIA.

We need not apologise to our readers for recurring to this subject, to which we referred in an annotation in The Lancet of May 31st, p. 1552, when noticing two excellent papers which had appeared in the *Indian Medical Gazette* for that month. The main interest of these papers consists in the fact that they are illustrative of the influence of local causes of tissue irritation in the history of cancer. We said that anyone looking over the tables of various forms of malignant disease (which in its broader sense may be taken as synonymous with cancer) compiled from the register of the General Hospital, Madras, for the past 10 years could not fail to be struck by the enormous number of native patients of both sexes admitted for carcinoma of the cheek, jaws, or tongue. Taken together these account for more than one-half of the total admissions. The frequency of carcinoma in this situation is, in the opinion of Captain W. J. Niblock, I.M.S., due to the chewing of "betel," a common habit in that country and indulged in by almost all classes of natives. "Betel" is made up of betel leaf, areca nut, and caustic lime (*chunam*) with certain condiments mixed together in varying proportions. Carcinoma of the cheek is particularly prevalent on the west coast—especially in Malabar—and this, again, is believed to be partly attributable to the fact that the betel used on the west coast for chewing contains a larger amount of caustic lime. As indicative, also, of the effect of continued local irritation as a forerunner of cancer it may be mentioned that no less than 201 patients were admitted for epithelioma of the penis, all of whom were Hindus. The non-occurrence of epithelioma in Mahomedans is ascribed to the fact that they are circumcised at a very early age.

whereas circumcision amongst Hindus is very exceptional and they are consequently more liable to suffer from any local effects arising from any retained and irritating secretions. It is also noteworthy of remark that in a table showing a total of 976 cases of cancer there were only 44 of the female breast. Turning to Dr. E. F. Neve's paper giving the results of "a decade of tumour surgery in the Kashmir Mission Hospital," we find that out of a total of 2020 tumours operated on more than 50 per cent. were malignant. Here again the results are illustrative of the action of some form of irritant on the particular area of the body affected. While there were only 29 cases of cancer of the female breast there were 363 of *kangri* "burn" cancer (epitheliomata). More than three-quarters of the epitheliomata were situated on the thigh, abdomen, or leg, and were clearly due to the irritation of a portable charcoal fire-basket (*kangri*) carried under the clothing in contact with the body. The result of this practice is first a burn and then irritation of the scar by heat, followed by an overgrowth of typical epithelioma, ulceration, and attendant glandular implication. It may be inferred from all that has been said that it is not to any blow or injury, but rather to the effect of an altered and perverted nutrition of tissue brought about by some chronic or recurring irritation that we must look for the source of cancer.

THE CHURCH ANTI-VIVISECTION LEAGUE AND HOSPITAL SUNDAY.

We have on previous occasions had to take the Church Anti-Vivisection League to task for issuing misleading circulars[1] and we have now had sent to us the following which we presume is being distributed to the clergy :—

> Church Anti Vivisection League,
> 14, Bonchurch road, Kensington, N.W., May, 1902.
>
> Reverend and Dear Sir,—On the approach of Hospital Sunday it has been for some time the habit as well as the duty of our League to press upon the attention of the clergy of London the tremendous responsibility which they incur by contributing offertories to the Mansion House Fund, while a very large portion of that fund is devoted to hospitals in whose medical schools tortures are inflicted on God's creatures with the sanction of the law, which, if committed elsewhere, would be visited with its severest penalties.
>
> Our League desires furthermore to draw your attention to the fact that not only does a very large portion of the money contributed by you go to the *indirect* support of animal torture, as well as of the system of experimentation on human beings, which is its logical and inevitable result; but that a small portion of the money which you venture to offer on the altars of that God of Love, before Whom not one sparrow is forgotten, is *directly* and avowedly employed in the torture of animals. It is true that this is a very small fraction of the total, but that does not alter the principle or the desecration of God's Altar therein involved.
>
> In addition to the solemn warning which we feel it our duty to record, our League has the more pleasing task of recommending a proposed hospital to which Christians need not scruple to contribute, and which will not try to reconcile two things so utterly opposed to each other that they are absolutely incapable of flourishing side by side—viz., Vivisection and Christianity.
>
> Yours obediently,
> Neville Dundas,
> Chairman, Church A. V. League Committee.

Can the League give us chapter and verse for any instance of experimentation, other than a trial of a new method of operating, on a patient in a British hospital as a result of vivisection? Can it, moreover, tell us in what hospital any portion of the Hospital Sunday Fund is, or has been, "*directly* and avowedly employed in the torture of animals"? From a notice of the proposed hospital inclosed with the above circular we learn that it will have an honorary medical staff of 26 members. Of these, as far as we can identify them by the current Medical Directory, we took eight at random. Of these eight one lives in London and, very inconsistently for a member of a staff of an anti-vivisectionist hospital, puts himself down in the Medical Directory as "Editor of Harvey on the Circulation of the Blood." Another of the eight lives in Norwood; another has apparently no qualification but the M.D. of Paris and hence is not on the Medical Register; the remaining five live in Gloucester (this one being a prizeman in physiology), Oxford, Bognor, Droitwich, and Falmouth. As the proposed hospital is to overlook Battersea Park the last-named gentleman will be a very hard-worked member of the staff. The proportion of clergy who take any notice of this misleading circular will be but small if any, but none the less it is disgraceful for a body which associates itself with the Church to issue such a document.

ANNUAL DINNER OF THE EPIDEMIOLOGICAL SOCIETY.

The annual dinner of this society was held at the Grand Hotel, Charing Cross, on June 6th, when the President, Dr. Patrick Manson, C.M.G., F.R.S., occupied the chair. Among those present were Dr. Theodore D. Acland, Dr. W. A. Bond, Sir Benjamin Brodie, Bart., Dr. H. T. Bulstrode, Dr. A. G. R. Cameron, Dr. C. Childs, Mr. J. Nield Cook (medical officer of health of Calcutta), Dr. W. H. L. Copeland, Dr. S. M. Copeman, Dr. W. H. Corfield, Dr. C. W. Daniels, Lieutenant-Colonel A. M. Davies, R.A.M.C., Mr. J. S. C. Elkington, Dr. W. W. E. Fletcher, Dr. J. S. Haldane, F.R.S., Dr. G. A. Heron, Dr. H. R. Kenwood, Mr. J. B. Lawford, Mr. C. P. Lucas, C.B., Dr. T. Glover Lyon, Mr. Shirley F. Murphy, Dr. J. T. C. Nash, Dr. A. Newsholme, Colonel J. Lane Notter, R.A.M.C., Dr. G. H. F. Nuttall, Dr. H. Franklin Parsons, Dr. Edward C. Seaton, Dr. P. Blaikie Smith, Dr. S. Squire Sprigge, Dr. E. J. Steegmann, Dr. S. W. Wheaton, and Dr. B. Arthur Whitelegge. In proposing the toast of "His Majesty the King" the Chairman referred to the great interest which the reigning monarch manifested in public health questions, notably the control of tuberculosis and cancer. The toast of "The Navy, Army, and Auxiliary Forces" was proposed by Dr. Theodore Acland and responded to by Colonel Lane Notter, R.A.M.C., the latter paying a high tribute to the humanity of our troops in South Africa. They possessed, he stated as a result of his recent extensive experience on the Enteric Fever Commission, a remarkable power of fraternising with the enemy when the actual fighting was concluded. Dr. Monckton Copeman replied for the Auxiliary Forces. The toast of "The Visitors" was proposed by the President-elect, Dr. W. H. Corfield, and responded to by Sir Benjamin Brodie, Bart. (a descendant of one of the founders of the society), Mr. C. P. Lucas, C.B. (Assistant Under-Secretary of State for the Colonies), and Dr. Squire Sprigge. Mr Lucas spoke in highly appreciative terms of the recent work which had been carried out in the colonies under the auspices of the Royal Society and by the London and the Liverpool Schools of Tropical Medicine and he assured the members of the Epidemiological Society that the work of preventive medicine had the warm sympathy of Mr. Chamberlain and of the Colonial Office. Such work would alone be worth all the support which could be accorded to it if only for the reason that it held out hope that the separation of husband and wife and of parent and child which residence in tropical climates so frequently necessitated, might in the future be less essential in consequence of improved sanitation in tropical settlements. The toast of "The Epidemiological Society" was proposed by Dr. Nuttall, lecturer on Preventive Medicine in the University of Cambridge, who, in the course of a highly interesting speech, referred to the enormous advances which were being made in epidemiological science, and he drew attention to the remarkable work which had been carried out in Havana in stamping out yellow fever Dr. Nuttall pleaded for a more united effort towards the study of disease by the epidemiologist, the bacteriologist, and the statistician. Disease had many aspects, and the more sides from which it could be approached the better. Dr. Patrick Manson, President of the society, in replying to this toast, touched upon the valuable papers which were read during the past session.

---

[1] The Lancet, May 30th, 1896, p. 1506.

and he reported that the society had recently elected a large number of foreign and colonial secretaries from whom important contributions to the study of epidemiology might reasonably be expected. In urging the need for more extended epidemiological research in our vast colonial possessions Dr. Manson described in very happy terms the chaotic and untrustworthy condition of nomenclature and death certification in various parts of our empire. In announcing that the Council of the Epidemiological Society had decided to bestow its Jenner Memorial Medal, which was founded at the Jenner Centenary by public subscription, upon Dr. A. Laveran of Paris, the President referred to the peculiar gratification it gave him to occupy the presidential chair at a time when the medal was bestowed upon the discoverer of the plasmodium malariæ. As to the importance and far-reaching effect of Dr. Laveran's work there could be no question, and of all living epidemiologists none was more worthy of honourable recognition by the society than was Dr. Laveran. Dr. Whitelegge, H.M. Chief Inspector of Factories, proposed the toast of "The Chairman," which was most cordially received. Dr. Manson replied and proposed the health of Dr. Bulstrode, the joint honorary secretary of the society, who briefly responded.

THE DESTRUCTOR NUISANCE AT TORQUAY.

IN the issue of THE LANCET of May 17th, p. 1416, we commented upon the report of Mr. George E. Davis of Manchester, the expert employed by the Torquay Town Council to report upon the alleged nuisance caused by the destructor. Although the Town Council at the meeting on May 6th professed itself quite satisfied various residents were of opinion that the noxious smells still existed. At a meeting of the Destructor Committee held on June 3rd letters were read from Dr. Henry Humphreys and from the Misses Tapper complaining of smells caused by the destructor. Dr. Humphreys asked to be allowed to inspect Mr. Davis's report but the committee refused. Mr. Alderman Cumming said that in refusing the committee was following the instructions of the council, while the mayor, in reference to the question of publishing the report, is reported as saying: "This is one of those questions in which you must trust the committee. There is really nothing to keep back but it is not thought the best thing to do. The committee is acting upon legal advice." As far as we understand the committee recommends the council not to publish the report, whereupon the council tells the committee not to publish it, and when any inquiring ratepayer makes himself a nuisance committee and council act on the Spenlow and Jorkins principle. The mayor, however, revealed the true inwardness of the matter when he talked about "legal advice." The committee further resolved that persons complaining should send a special message to the chairman or the borough surveyor the next time they found cause for complaint. Dr. Humphreys, writing on June 7th, tells us that he acted upon this recommendation with the following extremely unsatisfactory result. He applied to the chairman. "I went at 9.30 one evening to fetch him, as our house for three hours had been pervaded with the smell as of a dirty blown-out paraffin lamp. Arriving at the house I found it dark and shut up and I failed to make anyone hear my ring. Writing the next day to the town clerk to ask when and where the gentleman was to be found I had to wait a fortnight before I got an answer. Hence the proposed procedure is likely to be very successful in causing further procrastination, which I suppose is really its object." It is, we think, evident that the nuisance is by no means abated and we advise the Town Council to publish the report, to take the ratepayers into its confidence, and to try to make the beautiful town of Torquay worthy of its reputation as a health resort and of the unrivalled scenery in which it stands.

THE MIDWIVES BILL.

ON Friday, June 6th, the House of Commons devoted several hours to the consideration of the Midwives Bill as amended by the Grand Committee on Law, when an important modification was introduced. For an amendment moved by Mr. Ambrose and seconded by Mr. T. P. O'Connor, aiming at the abolition of the Gamp, met with the approval of the House. As the first clause now stands a woman uncertified under the Act is not only prevented from assuming the title of midwife, but is also prevented from practising the habitual rôle of midwife for gain. This is an alteration in the Act which we have already stated to be necessary. The Home Secretary, however, took serious objection to the amendment and has almost intimated his intention to oppose it at a later stage. This attitude of Mr. Ritchie was not unexpected. For on Tuesday, June 3rd, when a deputation representing the Council of the British Medical Association waited upon him and urged that the Midwives Bill left the parturient poor still at the mercy of dirty, ignorant women, he replied to the effect that there was no obligation on the part of the Government to interfere. The House of Commons has now interfered, and it remains to be seen what the Home Secretary will do. In the House of Lords it will be within his power either to have the amendment struck out or modified, or to have the whole Bill rejected.

THE DEVELOPMENT OF THE UNIVERSITY OF LONDON.

PROFESSOR E. H. STARLING delivered at the University College, London, the Foundation Day Oration on June 5th, in which he discussed the University of London under the title of "The Building of the University." He pointed out that the skeleton of the University was already present. The supreme ruling body, the Senate, contained representatives of convocations, of the faculties of teachers, and of various public bodies, and was guided in academic affairs by the advice of boards of studies appointed chiefly from among the teachers in the University. According to the scheme advocated by Professor Starling there would be under the control of the Senate, but administered by local councils appointed by the Senate, four or more University centres In these centres the main teaching and research of the University in all faculties would be carried out. In addition to these centres there would be a number of schools of the University which would preserve their autonomy but would direct their teaching according to the requirements of the University. Such schools would be mainly post-graduate in character in that it would be their office to graft on the general training and method acquired within the walls of the University itself the special professional training necessary to fit men for the pursuit of medicine, law, commerce, or administration. Among such institutions would be the 12 medical schools attached to the great hospitals of London, the School of Economics and Commerce, and various training schools, and, it was to be hoped, the great legal corporations which had so far failed to grasp the extent of their responsibilities in the formation of a legal faculty of the University. In any policy decided upon it must be remembered that the whole object of the University was the improvement of the mental training of their fellow citizens and not the distribution of degrees. The possession of a London degree by any man should be a sign that he had received a thorough training and was an expert in the subject of his degree and was not a mere bundle of second-hand facts. It was vital to the welfare of the country that as many as possible of its inhabitants should have received a thorough university training and should be competent to use their brains in the solution of the new problems which must continually meet them whatever might be their trade or profession.

M. COMBES

WE welcome in the new Prime Minister of France a member of our own profession. M. Combes was born at Roquecourbe, in the Department of the Tarn, a little village of which the red bricks of its bridge contain the inscription, "This bridge was built here." There has been a little tendency in France to rally M. Combes on the almost unnecessary precision of his fellow townsmen. As a matter of fact, however, he has lived little in the district of his birth and is much better known in the Charente Inférieure which he has represented in the Senate since the year 1885. He is a *docteur es lettres* as well as a doctor of medicine and he was at one time on the point of taking holy orders. Theology was to him a congenial subject and he has not only contributed a number of articles on it to the *Revue Contemporaire* but he has also written an important book entitled "Psychologie de Saint Thomas d'Aquin." The present mental attitude of M. Combes is supposed not to be favourable to the domination of the State by the Church, and his advent to power is looked upon as the prelude to an increased rigour in carrying out the laws at present in force which were passed mainly to ensure the control of the religious houses. M. Combes has had a distinguished career. He has several times been Vice-President of the Senate, he was reporter on the law of secondary education, and president of the commission which inquired into the Associations—the inquiry which led to the passing of the rigid law for the control by the State of religious communities and which practically led to the departure from France of many of them. M. Combes has held office once and only once before, when he was Minister of Education in the Bourgeois Cabinet in 1895. The internal politics of France are naturally entirely beyond our sphere of interest, but that fact by no means lessens the pleasure we feel in the knowledge that one who has had the most excellent training of a medical education should have been selected for an office of great importance.

DOWN DISTRICT ASYLUM.

THE report of the resident medical superintendent of the Down District Asylum for the year ended Dec. 31st, 1901, is being prepared for publication. The patients admitted during the year numbered 115. The number discharged was 59 and the number who died was 55. The number remaining at the end of the year was 579. Of the 115 admitted 99 cases were attributed to physical causes, 12 to moral, and four indefinite. In only six cases was alcoholic intemperance an assigned cause, although in a very large proportion of cases attributed to a distant "heredity" alcoholic excess was undoubtedly the exciting or immediate cause. The system of discharging patients "on trial" continues to find favour with the public and to reduce the number resident, besides inciting the patient to establish his will-power. The majority of deaths were caused by phthisis, heart disease, or dysentery. The average cost of maintenance per head has increased from £24 1*s.* 4*d.* to £25 6*s.* 1*d.*, which is still below the average cost (£28 2*s.* 7*d.*) of the Irish asylums for the last recorded year. The superintendent thinks that it is important for every reason that the more acute and curable cases should be treated with the utmost liberality, in order that they may not become life-long burdens on the resources of the asylum, and he quotes the case of an aged maniac who recently died in the institution and who had passed 36 years in asylums, costing perhaps £900, and adds that it is possible that had the treatment in the acute stage been on more liberal lines he would not have cost a tenth of the sum and with a far different result. Owing to the increase of the asylum population an assistant medical officer had to be appointed.

THE CONTAMINATION OF FOOD BY ROAD AND BY RAIL.

IT requires no very searching inquiry to establish a very disgusting practice that goes on in regard to the carriage of vegetables from market gardens to London and provincial towns. From time to time complaints have arisen very properly as to the sources of contamination to which milk in particular is exposed in transit. In such a case the risk of contamination is not always obvious to the eye, but in the case of vegetables the risk is patent enough, as must have intruded itself upon the notice of any person gifted with the smallest faculty of observation. It is quite common knowledge that many, at any rate, of the market carts which bring vegetables to London do not leave London again empty. That fact alone is not disturbing, but when, as may be easily observed, the cargo of the returning carts is dung and sometimes offal and other filth only to be discharged once more in favour of vegetables without any attempt at cleansing, not to say disinfecting, it is time to protest and to stir up our sanitary authorities to insist upon strictly clean measures in this regard being observed. The same thing is true of railway trucks. Railway wagons employed for conveying filthy garbage into the country are sent back to London uncleansed and yet loaded with a consignment of all sorts and conditions of loose vegetables. No scientific investigation is needed to reveal the grave possibilities to health which such a slovenly and slipshod proceeding is likely to incur. Everybody must admit that it is disgusting and we earnestly commend all sanitary authorities to look into this matter and to put a stop to what can only be viewed as a flagrant and loathsome disregard for cleanly practices.

THE SOUTH AFRICAN CIVIL SURGEONS' DINNER

ON the evening of June 9th, at the Hotel Cecil, there was a reunion dinner of the civil medical men who have served in the recent war in South Africa. Sir Frederick Treves, K.C.V.O., C.B., presided, the principal guests being the Director General and the Deputy Director General of the Army Medical Service. After the toast of "The King" had been proposed by the chairman and duly received with musical honours Dr A. Conan Doyle proposed the toast of "The Imperial Forces." For the foe in the late war he had nothing but praise and he thought that England might well be proud of the victory which she had gained. The man, however, to whom they owed most was that humble unit whose name was never heard, but that was the man who carried the war through to a successful conclusion. Those who came in contact with him in hospital found him the same cheery creature there as he was when plodding along the path of duty and he ventured to state that there was not one medical man who had served in the war whose ideal of life had not been raised by a contemplation of that man's heroism. The toast, which was coupled with the name of Surgeon-General W. Taylor, C.B., A.M.S., the Director-General of the Army Medical Service, was drunk with enthusiasm. Surgeon General Taylor, in his reply, referred to the great self sacrifice of the men, many of whom gave up positions of affluence to help their country in the time of need, some of them even sacrificing their lives in their country's cause. The civil branch of the profession had seen the work of the military branch in the field and had learnt something of the difficulties with which the men of the Royal Army Medical Corps had to contend. He hoped that the war would result in bringing together in closer touch the two branches of the profession. Surgeon-General A. H. Keogh, C.B., the Deputy Director-General, urged upon civil surgeons who had seen service in the war the wisdom of forming themselves into field hospital units, which he said had proved to be most important. During the evening, in reply to a message sent to him, the following answer was received from Lord Roberts who was dining in another part of the building: "Field-Marshal Lord Roberts begs to offer his best thanks to Sir Frederick Treves and the 100 civil surgeons from South Africa for their most welcome message of congratulation on the declaration of peace. All soldiers who served in South Africa will ever gratefully remember the valuable aid of the civil surgeons who so patriotically placed their services at the disposal of the State at a time of great emergency." Much praise is due to the honorary secretaries, Dr. F. E Fremantle and Mr. C Gordon Watson, for the successful way in which they carried out the arrangements for the dinner.

ALFRED HUGHES MEMORIAL AT KING'S COLLEGE, LONDON.

IN addition to the memorials which have been already established in Wales to perpetuate the memory of the late Professor Hughes his colleagues, friends, and students at King's College have also taken steps to keep him in remembrance. With the sum collected (£150) a suitable memorial tablet has been erected on the wall of the College chapel and the balance has been devoted to the foundation of an annual prize in books or instruments which will be called the Hughes Memorial Prize in Anatomy. The sad facts of Professor Hughes's death from enteric fever, contracted at Pretoria while he was engaged in superintending the Welsh Hospital there during the late war, will be fresh in the memory of our readers. All those who knew him need no reminder of his sterling character. Memorials such as those founded in Cardiff and at King's College will serve to keep his memory green and to point to those who come after the example of a great teacher and a sympathetic friend. A full list of the subscriptions will be published in the next volume of the King's College Hospital Reports.

A REMARKABLE RECOVERY FROM A BULLET WOUND OF THE BRAIN.

DR. THEODORE DILLER reports in the *Journal of Nervous and Mental Disease* for May a case of injury of the brain caused by a bullet wound which traversed the brain antero-posteriorly from forehead to occiput which is remarkable as showing the reparative processes of nature and the extent of injury which the brain may tolerate. The case was that of a boy who, at the age of 13 years, was wounded by a bullet which entered just above the middle of the right eyebrow and made its exit five millimetres to the left of the occipital protuberance. Unconsciousness followed the injury and lasted for three weeks. Hernia cerebri occurred at the site of the wounds and fragments of bone had to be removed before healing took place. When the patient regained consciousness he was found to be speechless and completely paralysed on the left side of the body. Speech, however, returned at the end of four or five weeks and the paralysed leg gradually regained some degree of power during the next three years. At the age of 24 years, 11 years after the injury, the patient seemed in good health. The brain could be felt pulsating beneath the cicatrices of the wounds. He exhibited no mental defect and was able to walk with a limp as the left leg was quite spastic. All power of motion in the left hand and forearm was absent but limited voluntary movement of the left shoulder was possible. There was marked contracture of the fingers of the affected hand and stereognostic sense—i.e., the capacity of recognising solid objects placed within the grasp of the fingers and with the eyes closed—was lost. There was partial paralysis of the left side of the face. All forms of sensibility were greatly diminished on the left half of the body, the anæsthesia being complete in the left hand and arm. The tendon reflexes on the left side were also much exaggerated. There was also present a left-sided hemianopsia. The sensory and kinæsthetic paralyses were due to a lesion of the sub-Rolandic region of the internal capsule, while the hemianopsia was attributable to destruction of the cuneus or of the optic radiations within the cerebrum.

LADS' DRILL ASSOCIATION.

THE Lads' Drill Association, of which the Prince of Wales is the patron, was founded in 1899 with the object of introducing systematic physical training into schools and forming cadet battalions and corps throughout the country. In this work the association has been very successful, and on June 7th an opportunity was given to the public of witnessing a display of physical training held under the auspices of the association at the Royal Albert Hall when the Prince and Princess of Wales were present. 12 squads, each squad consisting of 48 children from elementary schools in various parts of the country, assisted in the display. Colonel Fox, who, as our readers know, has done excellent work with regard to the physical training of army recruits, has advised and assisted in the preparation of the exercises. The address of the honorary secretary of the association is 4 St. Kilda, Ridgway, Wimbledon, S.W.

PREVENTIVE MEDICINE IN INDIA.

THE year 1900, for which the Annual Report of the Sanitary Commissioner with the Government of India is the last published report, forms the closing year of the century and advantage has been taken of the fact to call attention to the progress which has been made in the sphere of preventive medicine in India. Great as this has been there is no reason why it should not be still greater in the future with a more highly developed sanitary organisation and a more extended application of sanitary science than exist in India at the present time. The great difficulty that has to be surmounted in dealing with an Indian population arises from the poverty and inherited social, racial, and class prejudices of the masses of the most docile but conservative people in the world. Scrupulous in the performance of the rites of religion and daily life, which often, happily, are based on elementary principles of personal hygiene, they make little or no corporate effort and cannot understand or appreciate the object and meaning of our Western ideas and civilisation, all of which are foreign to their notions, and some of which are practically unsuitable to the climate and conditions in which they live. Nevertheless, the natives of India are educable and changes in this respect are, though slowly, being gradually brought about as time goes on. There are numerous medical schools and universities in that country, medical and sanitary knowledge is spreading more and more widely, and the native rulers are, speaking generally, animated by an intelligent philanthropy. It should not, moreover, be lost sight of that, as far as we are ourselves concerned, sanitation as now regarded is a thing of yesterday as it were. The subject of practical hygiene as applied to armies originated with those who took it up after the Crimean war, and our knowledge was subsequently systematised and consolidated by Parkes who laid the foundations of a school of hygiene and whose inspiration, to quote the words of the Sanitary Commissioner's report, "has descended upon successive bands of students unto the present day." What has been achieved in India in the past century will be best appreciated by taking some of the mortality ratios set forth in a table of the report which is the source of our information. Taking, then, the death-rates per 1000 of European troops we find that in 1800–30 these were 84·6; in 1831–56, 56·7; in 1861–65, 26·95; whereas in 1896–1900 the death-rate was only 16·52. Among native troops the death-rate in 1879–83 was 23·95 and in 1896–1900 it was 11·81 per 1000. In the jail population, whereas the death rate in 1833–54 was 70·7 per 1000, it was for 1896–1900 only 29·97. There is much interesting information to be gleaned from the survey of a century of medical and sanitary progress in India and the work done is highly creditable to the medical services of that country.

THE CORONERS' SOCIETY OF ENGLAND AND WALES.

THE annual banquet of the Coroners' Society was held at the Holborn Restaurant, London, on Thursday, June 5th, the President, Mr. Henry J. Robinson, coroner for Lancashire, being in the chair and a large number of coroners and their guests being present. Justice having been done to an excellent repast the President submitted the usual loyal toasts which were duly honoured. Mr. Henry White, the senior vice-president and coroner for Winchester, then gave "The Imperial Forces" coupled with the name of Colonel Mitchell, V.D., the senior volunteer officer in the Kingdom, who replied in an effective speech. The toast of "The Coroners' Society" was proposed by Mr. W. Goldthorpe, chairman of the county quarter sessions, Salford, who referred to the great and good work that was done by coroners in keeping down many of the serious evils which afflicted the community, especially instancing their efforts in the reduction of infantile mortality. He spoke of the antiquity of the coroner's office and of the great aid which coroners rendered to the State. Alluding to the subject of "combination" he remarked that there were some combinations, such as "trusts," of which everyone, of course, did not approve, but he thought there could be no question of the value of such a combination as the Coroners' Society both to coroners themselves and to the inhabitants of England and Wales. He concluded an interesting speech by paying a personal tribute to the work of the President of the society. Mr. Robinson, in responding, referred with much humour to the disputed question of "viewing the body" and with great seriousness to the evils which were encountered by coroners and which they did their best to repress. "Our Guests" was proposed by Mr. S. F. Butcher, vice-president and coroner for Lancashire, and acknowledged by Dr J. G Glover, Mr. R. Melville Beachcroft, L.C.C., and Mr. Noel Humphreys of the Registrar-General's Department, the last-named gentleman referring especially to the question of death certification. Amongst others present were Sir W. H. Hornby, Bart., M.P., Mr. Luke White, M.P., Mr. G. H. Radford, L.C.C., Dr. Danford Thomas, and Mr. Arthur C. Langham, the late treasurer, who was presented at the annual meeting with an illuminated address recording the thanks of the society for his valuable services and regretting his resignation. "The Officers of the Society" was given by Mr J. C. Malcolm, past president, coroner for Leeds, who made a feeling allusion to the loss so recently sustained by the society in the death of Mr. Braxton Hicks who was not only a vice-president of the society but their most indefatigable and valued secretary. He also referred in appreciative terms to Mr. Walter Schröder, deputy coroner for Central London, in acceding to the request of the society to undertake the duties of honorary secretary in a time of difficulty. The toast was replied to by Mr. Schröder, the newly-appointed secretary, who said that although up to that morning when he attended the Council meeting he had not intended to accept the office of secretary, when he found that 19 of the council had come down to nominate him and several of the remaining seven had written to the same effect and then at the annual meeting in the afternoon the members were unanimous in repeating the request, he felt he could not refuse such an honour but must accept the office at all events temporarily. He also paid a graceful tribute to the memory of Mr. Braxton Hicks. Mr. G. Percival Wyatt, coroner for Southern London and Surrey, the newly appointed treasurer, also briefly replied. A programme of excellent vocal music added to the enjoyment of a very pleasant evening.

THE PREVALENCE OF SMALL-POX.

THE figures showing the number of patients admitted to the hospitals of the Metropolitan Asylums Board for the past week are as follows.—On Saturday, June 7th, there were 19 fresh cases; on Sunday, the 8th, there were 17 fresh cases; on Monday, the 9th, there were 42 fresh cases; on Tuesday, the 10th, there were 18 fresh cases; and on Wednesday, the 11th, there were 17 fresh cases. In the county of Essex there were during the month of May 162 cases of small-pox notified to the sanitary authorities and for the week ending June 7th there were 33. A useful leaflet has been issued by Dr. J. C. Thresh, medical officer of health for the Chelmsford Rural District, giving an account in plain, simple language of the early symptoms of small-pox and pointing out the desirability of calling in medical aid when any of these appear. A list of the public vaccinators is given and it is noted that revaccination may be obtained free of charge.

MENSTRUAL ERUPTIONS RECURRING IN SITU.

AMONG the rarer phenomena which have been observed to recur in conjunction with menstruation are eruptions such as herpes labialis, an erysipelas-like eruption of the face, erythema circinatum on the backs of the hands, fugitive erythema elsewhere, and purpura. At the meeting of the Société Médicale des Hôpitaux of Paris on May 23rd M. Henri Dufour described the following interesting case. A healthy but very nervous married woman, aged 42 years, had at every menstrual period for five years an eruption of round nummular erythematous spots which recurred *in situ*. The first spot appeared on the right side of the neck, was exactly circular, and attained the size of a two-franc piece. It always recurred *in situ* and was accompanied by five or six satellites which appeared later. At the three last periods a similar spot had appeared at the bend of the right elbow and at the end of the last period a spot had appeared for the first time on the back of the left hand. After some days the spots gradually lost colour. In the intervals between the periods slight pigmentation indicated the sites of eruption and in some places this disappeared entirely. The spots appeared the day before menstruation. Their evolution occupied eight days and they were accompanied by considerable smarting. At the onset they were accompanied by malaise, a febrile state, and headache. For some months the patient had noticed a disagreeable odour from the menstrual blood. Vaginal examination was negative. M. Dufour thinks that the recurrence of the eruption *in situ* is determined by the existence of a previous lesion on which the neuro-vascular phenomena of menstruation act electively. A little further development of the morbid process would cause hæmorrhage from the skin and the occurrences of similar spots on the mucous membranes would probably result in hæmorrhage. Hence the case furnishes a key to the explanation of vicarious menstruation and tends to show that in cases of this phenomenon there is a preceding lesion of the part which is its seat.

The disagreeable odour of the menstrual blood in the case related above suggests that the eruption was a toxic effect in connexion with menstruation. In the discussion which followed M. Barié referred to a case of "yellow catamenial chromidrosis" which he had described.[1] Two days before menstruation one hand became painful; then it became covered with large dark-brown spots which were especially marked near the middle of the dorsal surface and on the median part of the palmar surface of the first two fingers. This phenomenon was so regular that the patient could foretell the appearance of menstruation 48 hours before. The chromidrosis lasted 12 or 24 hours and then disappeared. The right and left hands were alternately affected with perfect regularity.

A DINNER OF OBSTETRICIANS AND GYNÆCOLOGISTS.

ALL medical practitioners interested in obstetrics and gynæcology are cordially invited to attend a dinner to be held on June 24th, at 7 P.M., at the Whitehall rooms of the Hotel Métropôle, under the chairmanship of Sir John Williams, Bart. On the same day, at 4 P.M., at 20, Hanover-square, in the rooms of the Royal Medical and Chirurgical Society, a reception will be held by Sir John Williams, Dr. Peter Horrocks, President of the Obstetrical Society of London, and Dr. Halliday Croom, President of the British Gynæcological Society. Application for the dinner tickets, price £1 1*s.*, should be made to Dr. Eden, 26, Queen Anne-street. A highly representative and influential list of stewards has been secured.

COMPULSORY INSTRUCTION IN THE ADMINISTRATION OF ANÆSTHETICS.

THE announcement that the Society of Apothecaries has included anæsthetics among the subjects in which it requires students to receive instruction before proceeding to its examinations is one step further in the direction of the general adoption of this necessary precaution. The Royal College of Physicians of London and the Royal College of Surgeons of England have already made anæsthetics a necessary part of the curriculum upon which they insist and the Board of Advanced Studies of the University of London has advised the Senate of that institution that a course of instruction in the administration of anæsthetics should be scheduled among the compulsory courses demanded from candidates for the M.B., B.S. degree. The General Medical Council was, we believe, approached by the Society of Anæsthetists some time since and petitioned to render a course of anæsthetics an essential in every curriculum before it was acknowledged as competent to ensure registration. The Council, it is to be regretted, has preferred to lag in the rear of the corporations rather than at once to take the leading position and to insist upon a reform which has commended itself to thoughtful practitioners for some years. That it is desirable that all students should be thoroughly taught the general uses of anæsthetic agents and not merely be instructed by seeing a senior hospital officer habitually employ one anæsthetic by some routine method seems too much of an axiom to need pressing home. We fully recognise the immense service which experimental physiologists and chemists have done in forwarding our knowledge of anæsthetics, but it is indisputable that unless the knowledge so acquired can be applied by the hospital teacher to the needs of the students little benefit will accrue to the public. It is only the exceptional student who reads monographs upon the physiological aspects of anæsthetics, and the man who needs most instruction is not the exceptional student. The average aspirant for a pass qualification contents himself with a hasty reading of a few paragraphs in the book upon pharmacology which he studies and makes little more effort to acquire a practical knowledge of anæsthetics. Now, however, that the corporations have adopted this forward step and insist upon a course of instruction in anæsthetics the responsibility of making that course at once practical and yet including in its purview a *résumé* of the very large amount of theoretical knowledge which has within the past 50 years been accumulated must rest with the hospital authorities and ultimately with the teachers. It will in the future become the duty of election committees of hospitals when appointing an officer whose duties include the direction of the department of anæsthetics to consider, not only the skill of the candidates as expert anæsthetists, but their knowledge and ability to impart both the knowledge and its practical application. This responsibility is one of no slight kind and involves far-reaching consequences as far as the general public and the reputation of the profession are concerned.

SANITARY PROGRESS IN THE GOLD COAST COLONY.

BY the application of the first principles of sanitation there is no doubt that much can be done to make the Gold Coast country a place where white men can live and work. Of course, the existence of a good supply of fresh spring water for drinking purposes which can be kept untainted by the drainings of the swamps is an enormous advantage. Such an advantage is possessed by Mantraim Wassau. The medical officer of this place has just published his first half-yearly report upon the health of the inhabitants and the report contains some very interesting particulars in regard to medical administration and the ailments peculiar to the district. We understand that the Government of the Gold Coast Colony is now attempting to obtain accurate statistics concerning the health of the white population and has issued printed forms to be filled in quarterly by the managers of mines and others giving information as to illness and deaths with their causes. One drawback to the district is that the land is practically uncultivated and the supply of good food is deficient. It is hoped by the establishment of experimental plots that the food-supply will become more plentiful and more interesting. At present tinned foods are the chief resource, although native fowls, mostly bone and skin, may be had for a few shillings, and occasionally a very small sheep is purchasable but the mutton is usually tough and tasteless.

FRACTURE OF THE FIFTH METATARSAL BONE.

SKIAGRAPHY is rapidly modifying the current teaching in regard to fractures and revealing the fact that lesions which are common have been previously overlooked. In the *Liverpool Medico-Chirurgical Journal* for March Mr. Robert Jones points out that fracture of the fifth metatarsal bone is apparently common though it does not seem to be mentioned in surgical literature. He relates a number of cases which he saw within a few months after sustaining this fracture himself. Case 1.—Whilst dancing vigorously he trod on the outer side of his foot, his heel being off the ground. Something gave way and he suspected that the peroneus longus was ruptured. With the help of a friend he managed to walk 300 yards. Next morning there was slight swelling over the base of the fifth metatarsal bone and pressure on the spot was exquisitely painful. Crepitus could not be obtained. The slightest pressure of the weight of the body on the toes was painful, and when the pressure was thrown on the outer side of the foot the pain was still greater. Extension of the ankle and flexion of the toes were immediately felt at the base of the fifth metatarsal bone. Radiography showed fracture of the fifth metatarsal bone about three-quarters of an inch from its base. Case 2.—A man, aged 30 years, while fishing and stepping from stone to stone placed the whole weight of his body upon the inverted foot. He felt something crack in the ankle and limped home. Radiography showed the same fracture. Case 3.—A man, aged 54 years, in running to catch a train twisted his ankle. He could walk by placing pressure on the heel and inner side of the foot alternately. There were swelling and ecchymosis over the base of the fifth metatarsal bone but there was no crepitus. Radiography showed the same fracture. For many years Mr. Jones has observed cases with similar symptoms and suspected a fracture without being able to prove its existence. The symptoms are pain when the patient endeavours to put pressure on the toes or inner side of the foot and when he flexes the toes or attempts to invert the ankle. The seat of fracture is swollen and tender. There is generally no crepitus, deformity, or yielding on manipulation.

DISTRIBUTION OF PLAGUE.

THE weekly return of the Director General of the Sanitary Department in Egypt shows that for the period from May 19th to the 25th there were 53 cases of plague in hospital, 22 of which were admitted during the week under notice. All the patients were of the native population.

THE LONGEVITY AND CAUSES OF DEATH OF THE INSURED.

A VALUABLE contribution on the longevity and the causes of death in those insured in the Scottish Widows Fund has been published recently by Dr. Claud Muirhead, the medical referee to the company. During the period of 21 years covered by the report—viz., from 1874 to 1894 inclusive—the total number of deaths among policy holders was 9791 and of these 9163 comprised males—nearly all being of English, Scotch, and Irish nationality in descending order of frequency. A number of interesting conclusions were reached from a careful study of the data collected concerning these cases. "Consumption," says Dr. Muirhead, "carried off our younger members in largest number, the average age at death being 42 years and during the 21 years under observation the mortality from it has happily been annually decreasing." On the other hand, cancer affected, it would seem, those of advanced years by preference, the average age at death being 60 years. The mortality from cancer among the assured seems to have been steadily on the increase during the period covered by the report. Of the total number of deaths 1273 were due to cardiac disease, 806 to phthisis, 799 to apoplexy, 667 to pneumonia, 539 to cancer, 461 to bronchitis, 454 to old age, 452 to diseases of the liver, 400 to renal disease, 175 to enteric fever, and the rest to other causes. It is interesting to note that suicidal deaths occurred in 127 cases—viz., 32 cases in the period 1874 to 1880 inclusive, 45 in the period 1881 to 1887, and 50 in the period 1888–1894. 17½ per cent. of all the suicides occurred within the first five years of assurance—viz., 7 per cent. in the first year, 3 per cent. in the second year, and the rest in subsequent years. Old age was given as the cause of death in 454 cases, or 5 per cent. of the total mortality, the average age at death being in these cases 81 years. Nervous diseases carried off 1767 persons, cerebral apoplexy being responsible for 799 deaths while the remaining 968 were due to other nervous diseases. The steadily increasing mortality from cancer among the assured points to the view that an increasing number of persons with a predisposition or tendency to cancer is to be found among the assured from year to year.

LORD ROBERTS will preside at the annual distribution of prizes to successful students of the St. George's Hospital Medical School in October next. It is anticipated that the occasion will see a considerable muster of old St. George's men who have been doing service in South Africa during the recent campaign.

THE distribution of prizes at the Charing Cross Medical School was made on Wednesday last, June 11th, by Sir Frederick Treves who testified to the excellent work that had recently been done by gentlemen attached to the school.

THE Glasgow University Club (London) will hold a dinner at the Trocadéro Restaurant on Tuesday, July 1st, at 7 P.M., under the chairmanship of the Very Rev. Principal Story. Ladies may be introduced as guests.

A MEETING of the Society for the Study of Disease in Children will be held on Saturday next, June 21st, at Manchester.

DR. F. W. HEWITT, anæsthetist to H.M. the King, has been appointed physician anæsthetist to St. George's Hospital.

Pharmacological Notes.

GUAIACOL PHOSPHATE.

F. G. EHLERT[1] describes guaiacol phosphate as existing in white, crystalline plates, devoid of taste or odour, insoluble in dilute alcohol, water, or oils, but freely soluble in chloroform and in strong alcohol. As to its therapeutic properties guaiacol phosphate passes through the stomach unchanged and is resolved into its components and absorbed in the intestines. It is eliminated principally in the urine. It is said to be much less toxic than either creasote or guaiacol as such and to exert a similar influence to that of these two drugs in cases of tuberculosis, typhoid fever, and other diseases. It contains 89·4 per cent. of guaiacol and is given in doses of from 1½ to 4 grains from three to four times a day.

DIGITALIS GRANDIFLORA.[2]

The galenical preparations of digitalis in the past have been derived exclusively from *Digitalis purpurea*, but the idea occurred to M. Golaz to prepare a dialysed extract of *Digitalis grandiflora*, which was found by Professor Kunz-Krause to contain 0·1348 per cent. of glucoside. The latter has attributed the action of *Digitalis purpurea* to digitoxin and digitalin (so named in Switzerland and in Germany, but known as *digitaleine* in France). Professor Kunz Krause finds that *Digitalis grandiflora* contains no digitalin and owes its activity to digitoxin, probably on that account it is more therapeutically active than is *Digitalis purpurea*. Dr. Schwarzenbeck considers it to be an excellent cardiac remedy. Professor Sahli (of Berne) and Professor Unverricht (of Magdeburg) have the same opinion. It would be useful to have further comparative experiments made as to the relative values of digitalin and digitoxin, since the question has not yet been definitely settled as to which of these glucosides is the more active.

THE COMPARATIVE VALUE OF THE PRINCIPAL SOLVENTS OF URIC ACID.

A. Vicario has recently published[3] an account of his researches on the relative solubilities of the various salts formed by the combination of uric acid with such substances as are employed for its removal from the human system. Besides the salts of the alkaline metals he has employed the newer organic bases—e.g., lysidine (methyl glyoxalidine), piperazine (diethylene-di imine), and formine (hexamethylene-tetramine), and their salts, lycetol (di methyl-piperazine tartrate) and sidonal (piperazine quinate). The results are of extreme interest and value. The neutral urates of potassium, sodium, and lithium are very soluble, but their instability, as is well known, hinders their formation in the system. Moreover, their solubility is notably inferior to that of lysidine, of di-methyl-piperazine, or other organic urates. The acid urate of calcium is less soluble at 37° C. than at the ordinary temperature and, contrary to the other mineral urates, is more soluble than the neutral urate of the same element. The acid urate of potassium is more soluble than that of sodium or even of lithium. It may be concluded that potassium bicarbonate would be a better solvent of uric acid than sodium bicarbonate or lithium carbonate. At a temperature of 37° C. (1) the acid urate of lithium is one and a half times more soluble than the acid urate of sodium; (2) the urates of urotropine and of piperazine are eight times more soluble than lithium urate; and (3) lysidine urate is 20 times, and di-methyl-piperazine 23 times, as soluble as lithium urate.

THE THERAPEUTIC EFFECTS OF DORMIOL.

MM. Besançon and Dumont[4] contribute an account of the therapeutic effects of dormiol. This compound, di-methyl-ethyl-carbinol chloral, is chloral modified by the addition of certain ethereal radicles, experience having proved that in certain products, notably the sulphonals, the introduction of these radicles develops to the utmost the hypnotic properties of the parent substance. Dormiol is an eminently hypnotic compound. It is a colourless liquid with a fresh taste and an odour resembling that of menthol. It is more hypnotic and less toxic than chloral. Its action is rapid and is not prolonged after the desired sleep has been obtained. This property renders dormiol superior to chloral and, above all, to sulphonal and trional, which provoke a sensation of heaviness and headache on the day following their administration. According to M. Besançon dormiol may with advantage replace chloral in cases of intractable insomnia, whether of neurasthenic or hysterical origin or due to alcohol. In spite of large doses of dormiol (45 to 60 grains) which have been given on several occasions these investigators have never observed any disorder either of the circulation or the respiration, and—a point of importance—have never observed the appearance of erythema, a not uncommon concomitant in the case of chloral. The sleep produced by dormiol is calm and free from nightmare; the awakening is normal and is unaccompanied by nausea or headache. Dormiol may be given in doses of from 15 to 60 grains in a draught composed of water and syrup.

SALICYLIC OINTMENT FOR SOFT CHANCRE.

E. Szanto[5] employs for this malady an ointment composed of salicylic acid one part, tincture of benzoin two parts, and soft paraffin 30 parts. The results are said to be excellent.

SUCCINIMIDE OF MERCURY IN SYPHILIS.

K. Horowitz of Vienna[6] recommends the use of succinimide of mercury in all forms of syphilis. It is a white powder soluble in hot water and may be made into solution and kept in bottles holding enough for one injection. Cocaine is added to prevent pain during the injection which should be intra-muscular. The solution contains succinimide of mercury 38¾ grains, cocaine hydrochlorate 15½ grains, distilled water 775 grains; it is filled into bottles each holding about three quarters of a grain of the mercury salt and about one third of a grain of the cocaine salt.

[6] Centralblatt für Therapie, quoted in Nouveaux Remèdes de Pharmacologie.

THE medical golf tournament was held on May 25th on the fine links of the Northwood Golf Club. There was a good entry of 76, almost equally divided between the two handicap classes. In the first division Dr. G. A. Sutherland, in receipt of five strokes from Bogey, returned the good score of all square and took the first prize, Dr. Percy Kidd and Dr. Vassie tying for second prize with two down. For the best result *v.* Bogey in the last nine holes Mr. Percy Furnivall, last year's winner, was a good first with one up on the "Colonel." In the second division, so good was the handicapping, three gentlemen tied with four down—viz., Dr. Seymour Taylor, Dr. A. Densham, and Dr. G. F. Buzzard. Bogey was beaten in the last nine holes, Dr. Andrew being one up and securing the prize. Dr. Densham was the winner on playing off the tie. A good entry for the Foursomes *v.* Bogey resulted in a win for Dr. Percy Kidd and Mr. Rolf Creasy at four down.

OBSERVATIONS ON DIET.

By HARRY CAMPBELL, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE NORTH-WEST LONDON HOSPITAL; PHYSICIAN TO THE WEST-END HOSPITAL FOR NERVOUS DISEASES, WELBECK-STREET, W.

III.—QUANTITY OF FOOD (*continued*).[1]

Safeguards against Over-eating.

Vomiting.—Sometimes an overloaded stomach relieves itself by disgorging its contents.[2] So-called "bilious vomiting," to which some are periodically subject, may also act as a safeguard against chronic excesses in eating. Attacks of this kind are generally associated with headache, and are, in fact, megrimous; they benefit not only by their mechanical effect on the liver—which effect, it is needless to say, may be very considerable—and by ridding the system of so much noxious material, but by securing a period of starvation, often for an entire day. Megrim may in this way be a blessing in disguise; but the attacks tend to diminish with advancing years and frequently disappear altogether by the time the degenerative period is reached—that very time, namely, at which a periodic fast is most likely to be of service. Not megrim only, but any kind of illness, may benefit by compelling abstinence and affording the organism at least a temporary respite from prolonged excesses. The gouty man gets his periodic upsets, which necessitate a break, however short, in his habitual indulgence, and there are few, even among those who live most carefully, who do not have their occasional bouts of "seediness," in which the appetite flags and less food is taken than usual. Even the gravest illnesses, such as enteric fever and cholera, may in this way be blessings in disguise. I have seen some remarkable instances of chronic dyspeptics entirely cured of their indigestion and improved in their health generally by a long and severe illness. No doubt part of the good effect may in some of these cases be due to the specific influence of the disease, and part to the prolonged rest which it entails, but it is at least highly probable that part also is attributable to the careful dietary and possibly partial starvation which the patient may have had to submit to.

Fasting.—I may refer in passing to the salutary effects, physical as well as mental, of religious fasting. One day's abstinence from meat in the week represents more than seven weeks' abstinence in the year, and more than 10 years out of 70.

I am tempted to digress for a moment here in order to draw attention to the difference between the effects produced by the continuous and the interrupted action of a morbid agent. The evil effect is always worse in the former case. As with drinking so with eating, it is the steady, uninterrupted, day-by-day excess which is so injurious, when the organism is allowed no respite, no opportunity of recovering itself, from the injury inflicted. A harmful practice which indulged in for a short time may cause no appreciable permanent injury may, if steadily persisted in, lead to serious evil. It is the old story of the drop of water and the stone. It is well known that drunken bouts, provided they are separated by fairly long intervals of complete abstinence, may work little lasting harm, and that it is the habitual sot who never gets drunk but who is never quite sober who suffers most from the effects of drink. Even small quantities of alcohol continued daily for years may be pernicious. A patient perhaps assures us that he drinks very little, but when the total yearly quantity is reckoned up it will give a surprisingly large amount. Even so moderate a quantity as two glasses of whisky a day totals 60 bottles in the year and 600 bottles in 10 years, and when it is reflected that the whole of this has to go through the liver, the dullest will perceive that there is plenty of opportunity for that organ to be damaged by the daily consumption of two glasses only and that an occasional abstinence for a few days, or even a day, would probably be beneficial. And what is true of alcohol is true also of tea, coffee, and tobacco, all of which tend to act injuriously and also of certain articles of diet, such as

The Milroy Lectures

ON

THE ETIOLOGY OF TYPHOID FEVER AND ITS PREVENTION.

Delivered at the Royal College of Physicians of London on Feb. 20th, 25th, and 27th, 1902.

BY W. H. CORFIELD, M.A., M.D. OXON., F.R.C.P. LOND.,

PROFESSOR OF HYGIENE AND PUBLIC HEALTH AT UNIVERSITY COLLEGE, LONDON; CONSULTING SANITARY ADVISER TO HIS MAJESTY'S OFFICE OF WORKS.

LECTURE II.[1] (*concluded*).

Delivered on Feb. 25th, 1902.

I NOW come to instances of outbreaks of typhoid fever which have been traced to the pollution of streams and rivers supplying drinking-water. Early in the "seventies" I traced a severe outbreak of about 180 cases of typhoid fever which occurred in the fishing village of Mevagissey (Cornwall) to the contamination of the stream running through the village by the excreta of a typhoid fever patient who had come there during an early stage of the disease.

In 1882 Dr. F. W. Barry reported on an extensive outbreak of typhoid fever at Bangor and its neighbourhood. He showed that this outbreak was due to an "*extremely well-marked case of enteric fever of a severe type* which occurred at a place called Llwynrhandir. The medical officer of health directed the inmates to bury all excreta, &c., and this they promised to do. From information, however, obtained from credible witnesses," says Dr. Barry, "I am convinced that nothing of the kind was done until a considerably later period when no doubt the discharges from this particular patient were buried in the garden. *The slops and washing water from this house are thrown into a sink at the back and pass by means of a covered rubble drain along the back of it and the house adjoining, where it discharges into a small rapid stream, which in its turn is conveyed as far as the boundary wall of the garden in a similar covered drain, and is thence conducted by means of an open ditch direct to the river Gaseg, into which it discharges at a point about 350 yards above the intake of the Bangor water-supply, the whole distance from the house to the intake being about 700 yards.* Upon removing some of the stone covers from a portion of the stream near the house a most offensive smell was perceived. The stream has an exceedingly rapid flow, so much so, indeed, that some whitewash which I poured into the sink behind the infected house could be traced for a considerable distance towards the Gaseg. It will thus be seen that there is a direct communication between the infected drain at Llwynrhandir and the small stream from which the Bangor water-supply is drawn and in this manner no doubt infected matter found its way into the filtering reservoir. The privy at Llwynrhandir is of the ordinary cesspool type; the pit is, however, below the level of the drain already referred to. As to the capability of the filtering material in the filtering beds at the waterworks for destroying or preventing the passage of infective matter we know little, and here the question need not be considered, because I found that from the presence of old defective plugs in the filters themselves fully a third of the water was passing direct into the watermain without any filtration whatever. The filtering sand has not been renewed for a great number of years, although I understand that it undergoes a certain amount of cleansing from time to time. I was further informed by the clerk to the urban sanitary authority, who is also the waterworks manager, that from the peaty character of the water the filters frequently become clogged, and at such time the water cannot be filtered rapidly enough to meet the demand, hence the water is passed into the mains without any attempt whatever at filtration. Here, then, we have established a direct means of communication between the consumers of water and the specifically poisoned contents of a drain at Llwynrhandir; further, we have cases occurring simultaneously miles apart from one another which, with the exception of the water-supply, had no circumstances in common, there being also an entire absence of cases in houses not so supplied. I have, therefore, now no hesitation in attributing the primary spread of the disease to the water-supply."

After describing the course of the outbreak he concludes as follows: "Taking all the facts of the case into consideration, it is my opinion that the water-supply became specifically infected to a slight degree on or about May 22nd, and that this pollution continued until the end of June. That this continuous slight pollution accounts for the dropping nature of the cases up to July 7th. That the special outbreak in the second and third weeks of that month was due to the communication of infected matter in a concentrated form owing to the disturbance in the reservoir and filter-beds, resulting from the accident to the main on June 30th. Finally, that a certain number of the cases which have occurred from the end of the first period to the present time are due to the direct introduction of infected air from the sewers into which the discharges from cases of enteric fever had been received" (Twelfth report of the medical officer to the Local Government Board for 1882.)

An outbreak at Mytholmroyd (Yorkshire) in 1888 was attributed by Dr. Page to pollution of the river Calder by the sewage of towns higher up its course. In 1891 Dr. Hubert Airy prepared a most important and comprehensive report on the Outbreaks of Enteric Fever in the Valley of the River Tees in 1890–91, in which he showed that these outbreaks were especially amongst the users of water from the river for domestic purposes, thus "it was found that the rate of attack from enteric fever per 10,000 living during the first six weeks' epidemic had been 33 amongst persons supplied by the Tees water, and three amongst persons supplied with other water; whereas in the second six weeks' epidemic the rates were 28 and one respectively. Indeed, during the two periods together for every single person who contracted enteric fever amongst the population not using the Tees water 15 contracted it amongst those who were supplied from the river." This river was liable both habitually and still more during floods to fouling by human excreta and other filth from the town of Barnard Castle and some 20 villages and hamlets. Commenting on this the late Sir R. Thorne remarked: "Over a wide area covering 706,020 acres, or 1103 square miles, and containing 503,616 inhabitants, enteric fever has for years past been unduly prevalent. Within this area, where the infective material is thus constantly ready to hand, there occur in 10 sanitary districts, covering 117,404 acres, and containing a population of 217,363, two marked and sudden outbursts of enteric fever, each of large amount, the remaining area meanwhile exhibiting, as regards its constituent sanitary districts, comparatively insignificant 'fever' rates. One of the outbursts is at a time of year when, apart from some exceptional and unusual factor, enteric fever is not apt to prevail in epidemic form in this country. Within the sanitary districts invaded by the two epidemic prevalences some localities suffer heavily whilst others escape exceptional incidence to the disease. One factor alone is found to be common to the places thus suffering exceptionally from enteric fever and this is the use of water pumped from the river Tees. This river is found to be at all times subject to conditions of the grossest fouling by reason of the fact that human excreta and other filth are knowingly and deliberately conveyed to it. Opportunities for the access of the specific material of enteric fever to the river had been constantly recurring. And immediately antecedent to the epidemic outbursts sudden floods washed vast masses of the filth which had been accumulating on the banks of the river down the stream up to and past the points of intake from which the water was being pumped and, after filtration through sand and gravel, delivered to certain populations. These populations it was who suffered from the two exceptional prevalences of enteric fever. Seldom, if ever, has a case of the fouling of water intended for human consumption, so gross or so persistently maintained, come within the cognisance of the medical department, and seldom, if ever, has the proof of the relation of the use of water so befouled to wholesale occurrence of enteric fever been more obvious and patent." (Report of the medical officer of the Local Government Board for 1892–93.)

In 1891 Mr. E. L. Jacob traced an outbreak of 25 cases at Catteshall Paper Mills, near Godalming, to the temporary use of the water of the river Wey for drinking. "At one of the meat and eggs, which may with advantage be abstained from occasionally.

---

[1] Lecture I. and the first portion of Lecture II. were published in THE LANCET of March 22nd (p. 793) and April 5th (p. 942), 1902, respectively.

Hæmorrhages.—Spontaneous hæmorrhage from the nose, rectum, &c., may relieve the plethora resulting from over-eating. Whether or not—and the point is a moot one—there is an actual increase in the blood-mass in these cases, it is certain that the flushings, giddiness, and other unpleasant symptoms which attend them are benefited by bleeding, spontaneous or artificial, and in the old days bleeding was resorted to in cases of this kind with great advantage. There can be no doubt that the periodic flux in the woman tends to counteract the evils of over-eating, and its occurrence may help to explain why women during their reproductive life are so much less liable to gout than are men. When spontaneous hæmorrhage occurs in consequence of over-eating we must regard it as the overflow from an over-stretched arterial system and, if external, we should freely encourage it, especially at the degenerative period of life, so as to guard against the danger of cerebral hæmorrhage; the higher the blood-pressure the more urgent should we be in the matter. As I write I call to mind a patient, aged 75 years, who has occasional epistaxis, accompanied by augmentation of an habitually high arterial tension. Now this man used, in his ignorance, to try to check the bleeding, a procedure which, it is needless to say, exposed him to the grave risk of cerebral hæmorrhage. I explained to him that the bleeding resulted from the giving way of an overstrained blood-tube and that it was an effort of nature to relieve the high pressure in the blood-vessels generally and not by any means to be interfered with. In such cases we should do all we can not to arrest but to promote the bleeding, if necessary even opening a vein; at the same time a brisk mercurial purge should be given and the diet should be reduced to starvation point.

Purgatives.—The evils of over-eating may be lessened by the free use of saline purgatives, a method systematically carried out at Homburg, Marienbad, and similar spas whither fashionable folk flock to be purged of the humours resulting from chronic excesses. Salines benefit not only by favouring the elimination of poisons but by diminishing the absorption of food. The periodic use of blue pill and black draught is a favourite practice among habitual gourmands.

Reduction of Diet as a Therapeutic Measure.

How to deal with a case of over-eating.—If a patient is eating too liberally we should obviously aim at reducing the diet to a sufficiency, how to determine which has been already set forth—first decide what is the normal weight and then find the minimum quantity of food needful to maintain it. It is generally advisable to reduce the amount of food gradually. Thus we may tell the patient to omit every second course in the principal meal, never to take a second helping, to leave off eating directly a feeling of moderate satiety sets in, &c. But the patient may not consent to have his diet limited, and in this case we have to be content to counteract as far as we can the evils of over-eating by urging an open-air life and abundant exercise, and by resorting to blue pills, salines, and even, it may be, to bleeding. If the appetite is inordinate, as in gourmands it so often is, we should recommend plain, monotonous food and the avoidance of dishes calculated to tickle the palate; or we may seek to blunt the appetite by getting the patient to take a glass of milk, a piece of bread-and butter, or something of the kind, just before the main meal; or again, we may try to cheat the stomach, as it were, by the free employment of food containing a large proportion of unabsorbable material—e.g., green vegetables, which by their mere bulk create a feeling of satiety.

Periodic fasting.—The good effects resulting from periodic fasting have already been referred to and we should not be slow to turn this practice to full therapeutic account. Food may, for instance, be withheld for the entire day, or a single meal may be omitted, or meat, eggs, or other articles of diet may be temporarily abstained from. Especially should this plan be followed by those large feeders leading sedentary lives who are not obliged by attacks of megrim or other indisposition periodically to fast. Those engaged in laborious occupations, on the other hand, bear starvation ill. A plan of fasting which sometimes yields good results is the omission of breakfast. It has been widely advocated in America. I have heard of a medical man who does not allow anything before 11 A.M., at which time the patient is directed to take only a warm decoction of chocolate husks—presumably a device to give the stomach rest and to wash out the tissues by a harmless fluid, while at the same time the patient is influenced through his imagination.

Obesity.—The treatment of obesity is essentially by cutting down the diet and enforcing exercise. A simple reduction of the total quantity of food may suffice, but the most effectual plan is to eliminate fat and saccharides as far as possible from the dietary, the patient subsisting mainly on proteids, green vegetables, and fruits. The curtailment of fluid does not favour the absorption of fat, as some have supposed, but it may lead to a rapid diminution of weight at the beginning of treatment by diminishing the quantity of fluid in the tissues, and it may legitimately be resorted to for a time in order that the patient may be duly impressed with the progress he is making and encouraged to persevere in the treatment. Even those who are only slightly above the normal weight, say one stone, may sometimes be greatly benefited by having their weight reduced to the normal. One stone less to carry about the world is no small gain—e.g., to an elderly man whose heart and lungs are working to the utmost limits of their capacity. But though we may often improve our patients in this way we may find it difficult to persuade their friends as to the wisdom of our treatment, which they are wont to stigmatise as lowering, especially when plump red cheeks become hollow and lose their ruddy colour. "Whatever is the matter with you?" they will say, "you are not looking half so well as you did." Well, appearances are often deceptive, and in nothing more so than in regard to health. A plump face and a good colour pass with the laity as evidences of robust health, though the possessor may be on the verge of an apoplectic fit or in the last grip of granular kidney. On the other hand, a thin pale face is thought to indicate extreme delicacy, if not some grave disorder, while as a matter of fact it may go along with long life and sound health and merely betoken passing fatigue. It is necessary to impress such facts as these on over-solicitous friends. In reducing weight we must have due regard to the rate at which the reduction is effected. With some it is possible to proceed much more rapidly than with others; we must be guided by the condition of the patient. As a rule the loss of weight is most rapid at the beginning of the treatment; sometimes two or three, or even four, pounds may be lost in the first week without any ill effect, but it is seldom advisable to keep this rate up long and we should for the most part rest content with the loss of one to two pounds per week. The administration of thyroid extract in some cases greatly facilitates the absorption of fat, and it is, of course, most likely to do so in those who are myxœdematously inclined.

Dyspepsia.—Dyspepsia being frequently the result of over-eating it may often be cured simply by cutting down the diet. In the more acute forms it may be advisable to allow the alimentary tract complete rest by temporarily withholding all food, or at least by giving a very small quantity only, or by relying for a time on rectal feeding alone. It is especially in case of chronic dyspepsia in large feeders that the plan of foregoing breakfast above alluded to does good.

Lung disease—Dyspnœa.—In treating affections of the lungs, more especially when dyspnœa is present, the utmost caution should be exercised in regard to the quantity of food allowed. With the exception of certain cases of phthisis, in which gorging for limited periods may undoubtedly do good, we may broadly say that in all the serious inflammatory affections of the lungs not one single grain of food over and above the bare sufficiency should be given.

Consider for a moment what dyspnœa, that urgent symptom common both to heart and lung disease, indicates. It signifies a dearth of O and an excess of CO_2 in the blood, the former being the chief factor in causation: the patient hungers for oxygen. Now such being the causation it is manifest that in treating it we should reduce to the utmost the need for O and the production of CO_2, and the best way to do this is obviously by retarding combustion. This retardation is effected by securing rest, keeping the patient warm, and curtailing the quantity of food. Rest and warmth by diminishing katabolic activity reduce to a minimum the quantity of food constituting a sufficiency, and the advantage of this cannot be exaggerated, for, as I have already insisted, the greater the quantity of food consumed the greater the quantity of CO_2 produced and the greater the need for oxygen. Let us ever remember, when we see a patient gasping for breath, that every particle of food over and above the bare sufficiency must inevitably increase his distress, and this not only in the way indicated but by putting extra work on the heart at a time when it is imperative to save it as much as possible. We should also in these cases be careful to choose a non-flatulent diet, for a flatulent abdomen thrusts up the diaphragm, thus dislocating the heart, already in desperate straits, and crumpling up the lungs which are in need of every available air cell. Unhappily flatulence is especially prone to occur in dyspnœa and more particularly in the cardiac form of it.

A disease greatly benefited by spare diet is bronchitis, and especially that form which occurs in the aged and elderly, not only because excessive diet tends to aggravate dyspnœa, but because it promotes toxæmia, in itself a potent cause of bronchitis. When bronchitis occurs past middle life it is indeed in a large number of cases induced by over-eating and it is always aggravated by it.[3] In such cases we can often produce effects little short of miraculous simply by curtailing the diet, and nothing more strikingly shows how tardy our profession has been in the serious study of dietetics than its neglect of this simple fact. I feel assured that numbers of medical men have found it out for themselves, but I was not taught it, nor is it taught in the books, or generally acted upon, as I know by patients coming to me after consulting more than one physician. I must risk the charge of egotism in my desire to press home this important truth. Let me give notes of two illustrative cases.

CASE 1.—The patient was a man, aged 60 years; his weight was 13 stones and he was accustomed to eat and drink freely; he had a blue-red turgid countenance, dyspnœa, and rapid pulse; his liver was down to the umbilicus, his urine contained abundance of albumin, and his legs were œdematous. A somewhat gloomy prognosis was given to his friends. The patient was put on a severely spare diet and was ordered digitalis, iron, strychnine, and stimulating expectorants. After one week all dyspnœa had disappeared, the liver could not be felt, there was no albuminuria, nor was there any dropsy. At the end of six weeks the weight had fallen a stone and a half and the patient was hunting (not with my sanction), and he declared that he had not felt so well since he was a young man.

Doubtless the drug treatment helped here, but from a wide experience of similar cases I am convinced that the reduction in the diet was chiefly instrumental in bringing about the happy result.

CASE 2.—The patient was a man, aged 52 years; his weight was 12½ stones. He had for some years suffered from an irritating cough, apparently due to pharyngitis and slight laryngitis. The patient's diet was reduced to a bare sufficiency. No drugs were given. He steadily improved in his general health and the cough entirely ceased.

Asthma.—Among the affections which are benefited by a sparse dietary asthma occupies a prominent place. It is not easy to differentiate between that form which is wholly or chiefly of nervous origin and those forms which occur in failing heart and chronic bronchial affections, but whatever its origin improvement always follows from a reduction of the diet when the patient is a high feeder. Such has been my constant experience.

Heart disease.—I have already pointed out how important it is in all cases of failing heart not to give too much food. In plethora and high arterial tension, more especially when we apprehend the rupture of a cerebral blood-vessel, we must be careful not to allow the patient to eat one particle more food than is physiologically necessary, in extreme cases withholding all food for a time, administering a large dose of calomel, and if the pressure still keeps high resorting to free bleeding.

Aneurysm.—The urgent need of restricting the diet in the treatment of aneurysm needs no insistence.

Gout.—This affection being largely due to over-eating, the gouty should at all times be especially careful to take no more food than is just sufficient, and it may not only be necessary to cut down proteids but to reduce the amount of food all round. It should be remembered that even when a moderate quantity of proteid is being consumed an excess of saccharide and fat by "sparing" the proteid may cause the latter to be in excess; also, that bread and other cereal foods, as well as the pulses, increase acidity.

Nervous affections.—Many of the nervous affections due to over-eating, such as headache, giddiness, irritability, and asthma, may be of a gouty nature, but whether we regard them in this light or not—and the term is sufficiently vague,—the obvious indication is to reduce the diet. In some nervous disorders—e.g., epilepsy—the appetite may be voracious and we have to be on our guard against this.

Bright's disease.—In all forms of Bright's disease we should endeavour to lighten the work of the kidneys as much as possible, and inasmuch as their chief function is to eliminate nitrogen we should limit to the utmost nitrogenous food and to this end should administer a relative preponderance of "proteid sparers"—saccharides and fats; the total supply of food should, however, be no more than a sufficiency, inasmuch as in Bright's disease digestion and metabolism generally are working at a disadvantage, while the cardiovascular system is in most cases subjected to chronic strain owing to the augmented peripheral resistance.

Febrile states.—In extreme fever, when digestion is completely or partially in abeyance, especially when the patient has sunk into the typhoid state, it is a great mistake to worry him by the continual administration of nourishment. His instinct, which is wholly against food at this time, should not lightly be disregarded. Dr. F. J. Smith[4] does not hesitate to keep his enteric patients entirely without food for three, or even four, days when they are in a state of coma or delirium. More harm than good is done by forcing food into an unwilling stomach where it may remain for a long time undigested, thus adding to the distress of the patient.

Treatment by Giving an Abundant Diet.

Just as when the weight is above the normal we seek to reduce it by curtailing the diet, so when it is below the normal we endeavour to raise it by increasing the diet. "Always seek to get the patient down to, or up to (as the case may be) his normal weight." The physician who insists upon putting this simple principle into practice will not have lived in vain. Sometimes the proper weight may be obtained by an all-round increment of food, at others by an increase of the fat-forming foods chiefly, i.e., fats and saccharides; cod-liver oil and malt are generally helpful.

Patients below the normal weight benefit by rest, and we should therefore curtail their muscular activity at the same time that we increase their diet. The degree to which we do so will depend upon circumstances; in some cases a slight moderation in the customary daily activities may suffice, while in others it may be necessary to secure absolute repose in bed, in which case massage should be employed in order to maintain the tone of the muscles.

The following case shows what good may be effected simply by an all-round augmentation of the diet and a moderate curtailment of muscular activity.

CASE 3.—The patient was a man, aged about 48 years, who had for some months past been growing thin and suffering from indigestion. Being hypochondriacal and morbidly sensitive about his health he was greatly alarmed at his condition, especially when injudicious friends told him that he looked very ill and that he had aged much of late. Inquiry elicited the fact that he had been taking much more than his usual exercise in the belief that it was good for him—e g., he had walked home from business and had sat down to his dinner fagged and, his food not agreeing with him, he had been most careful to take only small quantities of the most easily digestible kinds. He was one stone below his customary weight. I said to him, "Get one stone heavier and your indigestion will go. With this object take as little exercise as your business will allow; eat as much wholesome food as you can; take cod-liver oil and malt thrice daily, and abstain from the use of all aperients" (to which he had been much addicted). The result was that the patient galloped along to health; his indigestion disappeared in a few days and his normal weight was regained in as many weeks. What most surprised him was the fact that he was able to get along without his pills.

Observe by what simple means the result was achieved. No single drug was given. It was simply a matter of augmenting the food and diminishing the expenditure of energy.

When once the normal weight has been reached in cases of this kind we must be careful not to allow the patient to continue on the augmented diet too long, or we may induce an entirely new order of troubles, and the older the patient the more urgent the precaution.

THE REPORT OF THE SANITARY COMMISSIONER WITH THE GOVERNMENT OF INDIA FOR 1900.

Concluding Notice.

In our former article[1] we briefly referred to the uncertainty and diversity of opinion which existed not only in regard to the etiology but as to the exact nature and pathology of the fevers prevalent in India and their differentiation from one another. As regards enteric fever, we alluded to the modern views and researches as to its bacillary origin, to the discovery and application of new diagnostic tests, and to the more enlarged and inclusive field of view by which a number of cases of fever were now grouped as enteric fever which some years ago would probably not have been regarded as coming under that head.

It is, however, the question of the liability of the native population of India to this form of fever that has of late been occupying the attention of the Indian medical press and concerning which the Sanitary Commissioner's report takes, but very cautiously, a somewhat new departure. If it could be demonstrated that enteric fever was a prevalent and widespread disease among the native population we need not go far to seek for the cause of its occurrence among the European garrison in its midst, for conditions favourable to its spread are abundantly present in India. That cases of enteric fever occasionally occur among the native races is undoubted. It has never been contended that any apparent immunity of these races is absolute but only that it is relative. It may well be, as is alleged, that a large number of cases of enteric fever are never diagnosed as such but are included and returned as malarial forms of fever or remittent fever; or that adult natives have acquired such immunity as they exhibit from the fact that they have already paid their tribute to enteric fever by having suffered from an attack of it in early life; or that the natives are immune because they have throughout their lives been brought up and surrounded by its etiological causes and conditions. But it is now alleged that the natives, as shown by the serum sedimentation reaction (Widal's test), do actually suffer from enteric fever to a far larger extent than has been hitherto recognised. If the correctness of this view can be established, and if it be granted that this disease runs a milder course in native subjects, and, further, if when it occurs among them it is usually incorrectly returned under the name of some other fever or disease, then it is urged that the etiology and pathology of Indian disease in respect of continued forms of fever and of enteric fever in particular will assume an entirely new aspect. And such would undoubtedly be the case, but the correctness of all this has yet to be established and the most that can be said about it at present is that it furnishes a good basis for further investigation and for the collection and weighing of evidence—of observations, facts, and figures, and not merely of opinions. The temptation to fill in the links in an incomplete chain of causation has always to be guarded against.

So far as they have gone hitherto the reports of the Sanitary Commissioner with the Government of India have year after year for a long series of years in succession shown two things: (1) a very marked and striking contrast between the European troops and the native army and jail population in regard to enteric fever with a disproportionately high-rate of case-mortality from fever generally among the former; and (2) a marked susceptibility on the part of the European soldier in India to contract, and to die from, enteric fever during the first three years of his service there, and notably during the first year. Speaking broadly, the disease from which the European soldier dies in India is enteric fever; that from which the native soldier dies is pneumonia or pulmonary disease. The etiology of typhoid fever is still an unsolved problem and direct evidence as to the modes of entrance of infection into the body is still incomplete, as will be seen by reference to a leading article on that subject in our columns[2] and to the recent observations of Dr. Thomas Cherry[3] of the University of Melbourne and other authorities. The bacillus coli and the typhoid bacillus, although readily enough distinguishable from one another, nevertheless belong to the same group and have many points in common, the gaps between them being bridged over by a series of intermediate forms. The periods of time during which typhoid bacilli can retain their potential infectivity within and without the body and, in hot countries, the action of dust, wind, and flies in their spread,—all these are directions in which much more light is needed than we possess at present, not to say anything about the long periods of time during which typhoid bacilli can exist without causing symptoms.

To refer, however, to another subject in the report under notice, we may remark, *en passant*, that with regard to abscess of the liver there are many points which still require to be cleared up before it can be said to be proved that the exclusive origin and cause of hepatic abscess is dysentery. Section III. of the report, which is a short but good one—especially in relation to the subject of fever (pp. 33 and 34)—is devoted to the native army of India and Section IV. deals with the jails of India. The former section contains some interesting information about the prevalence of such diseases in the native army as scurvy, tuberculous and pneumonic affections of the lungs, beri beri, and guinea worm, and the latter deals with the increase and spread of cerebro-spinal fever in the Indian jail population, tubercle of the lungs in relation to overcrowding, and other subjects.

The remaining sections deal with the vital statistics and diseases of the general population, vaccination, and sanitary works. Section IX., under the head of General Remarks, is devoted to the history and progress of preventive medicine in India during the century which has just closed, with the last year of which this report deals. The progress which has taken place is regarded as in a great measure the harvest of the inspiration and work of one man, Parkes, who laid the foundations of army hygiene, and in another and larger aspect as an important contribution to State economics. This section, which contains a great deal of compressed information, is well worthy of being read and considered. We hope to see the subject followed up, as is indicated will be the case, by a fuller statement of the work that has been done and the results that have been achieved by the medical services in India during the past century.

THE HEALTH OF MANCHESTER

The "housing question" as it affects the vast urban communities of the County Palatine has in recent years become a problem of pressing national importance as it is certainly one of great complexity. So precious for manufacturing purposes is any description of vacant building land in a populous neighbourhood, especially where it is traversed by a watercourse, that every available yard of the former is greedily seized upon by the speculative builder and forthwith covered with bricks and mortar; consequently large areas of property which only a few years since consisted of green fields have now become sites for labourers' dwellings, and in many instances what used to be a clear running stream has been degraded into a foul open drain for the conveyance of sewage or scarcely less noisome trade refuse. Thus it is that the map of Lancashire (as published in the recent census report) is almost completely dotted over with industrial centres, and as these are expanding rapidly in all directions the county will doubtless become at no distant date one unbroken expanse of manufacturing or of mining industry.

But what shall we say concerning the health of the millions of human beings clustered round these industrial centres? Have the local sanitary authorities been alive to their legal responsibilities in this regard? Have they taken care that the thousands of dwelling houses which under their very eyes have sprung up like mushrooms everywhere and which will inevitably be tenanted by the working classes, should be reasonably fit for occupation? Alas for our boasted system of local self government, we fear that, except as regards the larger municipalities, of which fortunately there are many admirable examples in Lancashire, this is far from being the case. For fear of offending what may be termed "local susceptibilities" the State permits speculative builders to cumber the land bordering on our chief municipalities with damp, ill-drained, and unventilated structures in which the veriest tyro could detect violations of the first principles of healthy house construction and which are therefore obviously unfit to live in. Consequently in the course of time the local ratepayers, panic-stricken at the first epidemic that ensues, are called upon to spend large sums of money to remedy evils which on the first covering of the ground might readily have been averted without real hardship to anyone. Figuratively speaking, in matters of sanitary administration it is in too many cases the practice not to close the stable door until after the steed has been stolen.

[2] The Lancet, May 24th, 1902, p. 1479.
[3] The Lancet, April 19th, 1902, p. 1141.

In such circumstances it is easy to comprehend how it happens that local building by-laws become a dead letter—how long rows of ill-drained, unventilated cottages, destitute of proper foundation, come to be crowded together on insufficient ground space, abutting on streets so narrow that access of sunlight and of air is alike impossible; in a word, how conditions obtain in which there is a glaring absence of those requisites which are known to be essential to the health and well-being of the people. In no other civilised country but our own would such a state of things as we have depicted be allowed to continue. The laws of health are simple and nowadays are fairly well known. To a certain extent these laws are embodied in existing statutes for the protection of the public health, and Parliament should see that they are not violated in the construction of dwelling houses for the labouring classes, whether these are situate in the country or in the suburbs of our chief towns.

We have received the annual report for 1901 of the medical officer of health of the City of Manchester—a volume of 340 pages—which is full of instruction for the student of preventive medicine. The report is one of a series which has attained uniform excellence and is complete in every department. We should like to see it adopted as a pattern by the medical officers of health of other cities similarly circumstanced to Manchester.

We have carefully studied this book and have thought it advisable to preface our notice of it with the foregoing remarks in the hope that they may explain some of the difficulties which an earnest and public-spirited authority like that of Manchester has to encounter in dealing with the accumulation of sanitary evils inherited from its predecessors.

The boundaries of the city of Manchester have been extended more than once since its original incorporation—the last time about 10 years ago, on which occasion a large area of extra municipal territory was annexed—and Dr. J. Niven's report contains interesting details concerning the sanitary condition of the newly-added districts referred to. These districts, before their inclusion in the city, were under the control of local boards and we are aware of no evidence to show that they were governed otherwise than according to the fashion which is usual among such authorities. Fortunately, they are now under the able administration of the city council and we have confidence that in future reports we shall have to note steady improvement in the conditions which obtain locally at the present time.

Leaving aside administrative details, which are mainly of local concern, the report before us is divided statistically into two portions—the first relating to the 10 years 1891–1900 and the second to the year 1901, to which the report more especially refers. Dr. Niven has availed himself of the recently published census figures to revise the whole of the populations on which his rates of mortality are based; this must have been a laborious process, but it is precisely the one that an officer of Dr. Niven's mathematical ability would regard as essential and we congratulate him on the expedition with which his results have been achieved. With the help of the newly-revised death-rates Dr. Niven proceeds to compare the mortality of Manchester and its constituent districts in the recently ended quinquennium with that of the quinquennium immediately preceding. Thus we find that in the entire city the average death-rate in the five-year period ending with 1900 was lower than that in the previous five years by 0·7 per 1000 persons living. This corresponds roughly to the improvement which was observed during the five years between 1893 and 1898 and if it were continuous the decrease would mean an improvement of 1·4 per 1000 in the death-rate of the last 10 years. Even in the old township of Manchester there is an improvement amounting to 0·3 per 1000, but this if continued will correspond to an improvement of double that amount in the 10 years. In South Manchester the improvement is still less, being 0·28 only, or equal to 0·56 per 1000 in the 10 years. In North Manchester the improvement is equal to 0·77 or for the 10 years to 1·54 per 1000 on the annual death-rate.

Coming to the individual districts of the Manchester township we find that Ancoats (in which district much old property has been recently demolished) shows a handsome improvement of 1·2 per 1000, or 2·4 per 1000 in the 10 years. The central district shows an average annual improvement in the quinquennium of 0·40 per 1000. St. George's, on the other hand, retrogresses to the extent of 0·8 per 1000, equal to 1·6 on the 10 years. Dr. Niven rightly observes that "this must be regarded as a serious recession."

We have not space to notice Dr. Niven's remarks on the variation in the death-rates of other parts of the city; we must accordingly refer our readers to the report itself, which will be found in the libraries of both of the Royal Colleges in London and consequently will be available to many of our medical brethren. For the same reason we are compelled for the present to pass over without notice several other portions of the report, notably Dr. Niven's timely and instructive remarks on the voluntary notification and hospital isolation of phthisis, his comments on return cases of scarlet fever, on the bacteriological investigation of suspected cases of diphtheria, and on the inter-relations between conditions of the soil and the spread of enteric fever. Dr. Niven's account of the work done by the Manchester Ladies' Health Society, by the Society for Visiting the Jewish Poor, and by the Special Jewish Health Visitor will prove instructive reading to those who contemplate the initiation of similar philanthropic sanitary work in other great centres of population.

In conclusion, we desire to congratulate the citizens of Manchester on their choice of a governing body which is not only keenly alive to the sanitary needs of the district but is resolutely determined to take no rest until the shortcomings of the city shall have been fully redressed, and we congratulate the city council on the possession of a medical adviser whose latest report proves him to be untiring in his efforts to promote the health and general well-being of the community.

THE METROPOLITAN WATER-SUPPLY: THE LONDON WATER BILL.

AT the sitting of the Joint Committee of the two Houses of Parliament on the London Water Bill on May 28th, Mr. FITZGERALD, K.C., on behalf of the Local Government Board, proposed a new clause drawn up in accordance with the recommendation of the Committee in regard to the question of arbitration. The proposed new clause was as follows:—

> The Court of Arbitration shall determine the sum to be paid to a metropolitan water company as if, with the necessary qualifications, the law of compensation for the purposes of the Lands Clauses Act was applicable to the case.

On behalf of the London County Council Mr. BALFOUR BROWN, K.C., proposed that the word "sum" should be substituted for the words "value of the undertaking."

Lord BALFOUR of BURLEIGH said that the committee had an objection to the word "compensation." No such objection was felt to the words "value of the undertaking to the vendor." The Local Government Board, however, objected to the words "to the vendor" because that form of words had not hitherto been so used in an Act of Parliament. A long discussion ensued and ultimately the committee decided that the form of words used should be as follows:—

> In fixing the sum to be paid by the Water Board as hereinafter provided the Court of Arbitration shall determine, the value of the undertaking of a metropolitan water company as if, with the necessary modifications, the law of compensation for the purposes of the Lands Clauses Act were applicable to the case.

Mr. LITTLER, K.C., on behalf of the water companies, proposed an amendment giving an instruction to the Court of Arbitration to make an allowance to the water company's shareholders as recoupment for any loss that might arise in finding an equally good investment yielding the same income as that paid by their present holdings in water companies' stock. Mr. Littler argued that the principle was clearly laid down by the Committee that they wanted everyone to be put into exactly the same position as they would have been had the Act not passed. The Court of Arbitration therefore should have power to effect this and the question should be dealt with in the Act itself. Under sub-section 9 no allowance was to be permitted for compulsory sale but it was reasonably fair that the shareholders should not lose the amount which might be necessarily spent to secure re-investment in a stock of equivalent value. Lord Llandaff's Commission had reported that "the dispossessed shareholders would be properly entitled to be recouped for the delay that might occur in finding an equally good investment yielding the same income as well as the cost of reinvestment."

Mr FITZGERALD on behalf of the Local Government Board, did not object to the principle but he objected to the wording of the amendment as proposed by the water companies He said that he was prepared to admit that the shareholders of the companies ought to have interest during the period taken up in reinvestment. The question had arisen because the committee had decided that payment was to be made in cash and not in water stock. He suggested that the words in the amendment should be, "Any loss of interest pending re-investment as well as for the cost of re investment and for covering any expenses which have been or are likely to be, incurred in consequence of the passing of this Act"

Lord BALFOUR of BURLEIGH in regard to the suggestion that the words used should be "an equally good investment yielding the same income" thought that the words might give rise to debate. Every member of the Stock Exchange might differ as to whether the conditions of the amendment were complied with. In reply to Mr LITTLER'S suggestion that this would be a question for evidence for the arbitrator, Lord BALFOUR of BURLEIGH said that he would be sorry for the arbitrator in such a case. The Committee accepted the amendment suggested by the Local Government Board.

Mr THESIGER, on behalf of the London County Council, proposed that the following words should be inserted at the end of sub-clause 9 —

> In any case in which any such allowance is claimed the items in respect of which such allowance is claimed and the amount claimed in respect of each such item shall be separately stated in the award

The object of this amendment was that the Water Board should know what claim was going to be made by each of the water companies in respect of these various extra items. This amount of protection for the Water Board was fair and the suggestion a moderate one on behalf of the London County Council.

Mr PEMBER, on behalf of the water companies, opposed the amendment.

Mr FITZGERALD, on behalf of the Local Government Board, did not think he could accept it and it was not agreed to by the Committee.

Mr PEMBER asked the Committee to make a declaration on a matter of principle. He would assume that they desired that all costs, charges, and expenses to which the water companies were put in consequence of having to sell their undertakings should be borne by the purchasers and that the "compensation money" for the value of their undertakings would be paid "clear"—that was to say, in full. In that case expenses connected directly or indirectly with arbitration expenses incurred in the winding up "and all the rest of it" would be paid by the purchasers.

In the Bill under consideration the sub sections 10 and 11 which apply to this matter are as follows —

> The costs of any metropolitan water company incurred in an arbitration under this Act shall, except and so far as the Court of Arbitration otherwise determine, be borne by the Water Board and the costs of any other person attending an arbitration under this Act shall be in the discretion of the Court of Arbitration, and that Court may order the taxation of any costs in such manner as they think fit
>
> The Arbitration Act, 1889 shall not apply to arbitrations under this Act

On behalf of the Local Government Board Mr FITZGERALD said that only costs "as between party and party" should be allowed by the arbitrators It was impossible to know what claims might be brought in under such a provision as that proposed by the water companies.

The amendment was rejected.

Mr LITTLER, K.C., asked the Committee to insert an amendment to provide that the arbitrators shall commence their sittings within six months after the passing of the Act.

The Committee decided to fix the time at a period of nine months

Clauses 19 and 20 of the Bill deal with subsidiary powers of the Water Board. Clause 19 was passed with some amendments Clause 20 gives power to the Local Government Board to make provisional orders. Some of the extra metropolitan authorities objected to portions of the clause on the ground that if passed it might be possible that power should be given to the Water Board to encroach on outside districts The portions of the clause which bore on this question were deleted.

At the sitting held on May 29th the chief matters which came under consideration were connected with the custody of, and property in the books and documents of the water companies and the fixing of the "appointed day" on which the properties of the companies would vest in the Water Board

The water companies contended that the property of the books and papers should vest in them until the end of the liquidation. The Committee decided that every book and document should belong to the Water Board but that the companies should have the most full, free, and perfect access to them for as long as might be necessary

In regard to the appointed day Mr LITTLER, K C, and Mr PEMBER, K.C, on behalf of the water companies, contended that it should be fixed at such a date that it would be morally certain that the arbitration would, when it arrived, be completed and the awards made On behalf of the London County Council Mr FREEMAN, K C, supported the date given in the Bill and Mr FITZGERALD K.C, on behalf of the Local Government Board, suggested that the day appointed should be Dec. 25th, 1903, or such later day (not being more than 12 months from that date) as the Local Government Board might appoint.

The Committee ultimately decided to accept the day suggested as the "appointed day" (Dec. 25th, 1903) and to give to the Local Government Board the power to postpone the "appointed day" to any date not more than 18 months afterwards—that is to say, until June, 1905.

At the sitting of the Committee which took place on May 30th Mr BALFOUR BROWNE, K C., on behalf of the London County Council, proposed that part of Clause 3 should be omitted from the Bill. The clause deals with the payment of dividends to companies until such time a water stock is issued and the part objected to by the London County Council is that which provides for the payment of such sums as may be agreed upon or determined by arbitration in respect of the reasonable expectations of increasing dividends It was contended that if prospective increase were to be taken into account prospective decrease should in like manner be taken into account also The Committee allowed the clause to stand The sub-section is as follows —

> The Water Board shall from and after the appointed day, pay by way of interest on purchase money to each metropolitan water company half yearly until the water stock to be issued to the company is issued a sum of money equal to the dividend on the ordinary and preference capital of the company calculated on the average rate of dividend paid thereon respectively in respect of the two half years preceding the publication of the notice for the Bill for this Act together with in respect of the reasonable expectations of increasing dividends (if any) such additional sums (if any) as may be agreed or in default of agreement as may be determined by arbitration under this Act

Section 36 of the Bill makes provision in regard to existing "officers and servants" of the metropolitan water companies It is as follows —

> 1 Subject to the provisions of this Act every officer and servant employed by a metropolitan water company upon or in connexion with the undertaking immediately before the appointed day (in this Act referred to as "an existing officer" and "an existing servant") shall as from the appointed day become an officer or servant of the Water Board and shall hold his office or situation by the same tenure and upon like terms and conditions under the Water Board as he would have held the same under the company if this Act had not been passed, and while performing the same duties shall receive not less salary wages or pay and be entitled to not less pension (if any) than he would have been entitled to if this Act had not been passed.
>
> 2. Every existing officer and existing servant shall perform such duties in connexion with the water undertaking of the Water Board as they may be required to perform by the Board
>
> 3. The Water Board may abolish the office or situation of any existing officer or servant which they deem unnecessary, and any existing officer or existing servant required to perform duties such as are not analogous, or which are an unreasonable addition to those which as an officer or servant of the company he was required to perform, may relinquish his office or service
>
> 4 Every existing officer or existing servant whose office is so abolished or who so relinquishes his office or service as aforesaid or who otherwise suffers any direct pecuniary loss in consequence of this Act shall be entitled to be paid by the Water Board compensation for such pecuniary loss regard being had to the conditions on which his appointment was made the nature of his office or employment the duration of his services and any other circumstances affecting the case
>
> 5. Subject to the provisions of this section the provisions contained in section one hundred and twenty of the Local Government Act 1888, relating to compensation to existing officers shall apply to any claim for compensation by an existing officer or an existing servant with the substitution of references to the Water Board and water fund for references to the County Council and county fund.

Professor Dewar, F.R.S., and Sir William Crookes, who are employed by some of the metropolitan water companies to report on the water supplied by them, gave evidence to the effect that they wished "for the purposes of compensation" to be deemed officers of the companies. They received from the companies about £1800 a year, and the amount left over after paying expenses was between £600 and £700 a year.

Mr. BRYAN and Mr. PARKES, engineers to the East London and Lambeth Companies, gave evidence in regard to the pensions and retiring allowances usually made by the companies to their officers and servants.

Lord BALFOUR of BURLEIGH said that the Committee wished that the officers and servants of the companies should be put into as good a position as they would have been if the Water Bill had not been proposed, and finally the settlement in regard to the clause was deferred and the remaining clauses of the Bill were agreed to.

At the meeting of the Joint Committee which was held on June 3rd the most important questions which were brought forward had reference to the protection of the inhabitants of the extra-metropolitan districts of Middlesex, of Kent, of Essex, and of East Ham. On behalf of the County Council of Middlesex it was proposed to insert a clause into the Bill to compel the Water Board to give to all the water consumers in the area of that county which is within the limits of supply water as ample in quantity and as good in quality as that distributed by the metropolitan water companies at the time of the passing of the Act. Further, the Middlesex County Council wished to ensure that the charges at present exacted by the water companies should not be increased in amount by the Water Board. They asked, moreover, that property in the county of Middlesex should not be subjected to any charge should the Water Board incur any expense by obtaining water from any new source of supply beyond the confines of the county of Middlesex.

The County Council of Kent wished that a clause should be inserted to ensure that nothing done in carrying out the Act should be allowed to prejudice any future application to Parliament by the Kent County Council for the acquisition by it of the means to supply those portions of Kent which are at present provided for by the Kent Company.

Lord BALFOUR of BURLEIGH, on behalf of the Committee, said that they did not approve the insertion of these clauses and their objection to them was that they were outside the purview of the Bill.

On behalf of the Local Government Board Mr. FITZGERALD, K.C., gave an undertaking to the effect that neither the Local Government Board nor the Water Board would found an argument against any future application which might be made to Parliament by the County Council of Middlesex or the County Council of Kent on the ground that the Committee had decided against them on the points mentioned above. [It is not easy to conceive how the Water Board, should such a body come into existence, could be in any way bound by any "undertaking" given by any learned counsel at the present juncture.] Ultimately, the clauses were withdrawn, and similar clauses which the Essex County Council and the authority of East Ham desired to introduce were likewise withdrawn.

The water companies proposed to introduce a clause into the Bill for the compensation of the water company directors for their loss of salary and Mr. BOULNOIS and Colonel LOCKWOOD, two water company directors who are Members of Parliament, gave evidence in favour of the clause.

Lord BALFOUR of BURLEIGH said that the committee accepted the principle of compensation to such directors as were in office at the date at which notices of the Bill were sent; the sum to be paid should be given after arbitration (for the expenses of which apparently the Water Board will pay).

A clause was proposed by the Urban District Council of Sunbury to ensure that for rating purposes reservoirs should be assessed at their full annual value and not, as at present, at one-fourth of this sum. A society called "The Association for Promoting the Equitable Rating of Reservoirs" supported this contention.

Lord BALFOUR of BURLEIGH announced that the Committee could not recommend that the general rating law should be amended at the present time in the manner proposed.

Looking Back.

FROM

THE LANCET, *SATURDAY, JUNE 12*, 1824.

SMALL-POX HOSPITAL.

On Thursday the Governors held their Half-yearly General Court at this Hospital. At one o'clock F. G. HANROTT, Esq. was called to the chair; and after the confirmation of the minutes of the last meeting, Mr. HIGHMORE the Secretary read the Committee's report, in which some legacies were stated, and a handsome testimony expressed to the meritorious services of Dr. GEORGE GREGORY, their physician, and to the assiduity of Mr. WM. WHEELER, their resident surgeon.

The officers and visitors were all re-elected; and Dr. G. GREGORY, the physician, presented a Medical Report, to which we are too conscious of not doing justice by the abbreviations which the pressure of our other numerous articles oblige.

It stated, among other things, that the arrangements made with the several adjoining parishes, particularly St. Giles-in-the-Fields, had caused an unusual number of infants and children to be admitted lately, with many of whom the disease had proved fatal; that of 151 patients in the last year 67 had been previously vaccinated; of these, in the ordinary course of the disease, and without the protecting influence of vaccination, 12 at the very lowest computation would have died. It must, then, be highly satisfactory to the Governors to know that the whole of these persons have been restored to society.—It is not indeed to be denied that seven of them suffered severely under the attack of the disorder, and that it required from four to six weeks for their perfect cure; but it is no light praise of vaccination to say, that even when imperfectly performed (and there was too much reason for presuming that such had been the case in most of these instances), it still had the power of mitigating the horrors of this dreadful disease, and of preserving life, even though it proved insufficient to resist the inroads of the contagion.—In one of the former cases it was ascertained by inquiries on the spot, that vaccination had been performed unskilfully and imperfectly, and that no reasonable confidence could at any time have been placed in it. The melancholy result of the case, however, will not be without its use, if it impresses upon all those who are engaged in vaccinating the indispensable necessity of a close attention to every stage of that process, upon which the safety of the individual in after-life so immediately depends. With most unfeigned satisfaction, he added, has the confidence of the lower orders of people in this town in the security which it is capable of affording, appeared to him greater than at present. Those whom a few unfavourable cases have impressed with an undue sense of the imperfections of the vaccine influence would receive an useful lesson by attending at this Hospital at the hours appropriated to vaccination: they would then learn to appreciate, in the grateful acknowledgments of thousands, the true value of that inestimable blessing which it was the glory of JENNER to have diffused; and though occasional failures will undoubtedly occur to warn us, like spots upon the sun, that nothing is perfect, yet to the eye that contemplates in a wide scale the results of vaccination, these are lost in the brilliancy of its general career, no where more conspicuous than in the annals of your useful and excellent Charity.

The meeting offered their united thanks to Dr. G. for this Report, and ordered it to be entered upon their minutes, &c.; and after expressing thanks to his Royal Highness the Duke of York, President, and to the Chairman, the Court separated.

It appears by the Bills of Mortality, that during the month of May, 32 died of small-pox, and six in this Hospital.

SYRACUSA CONVALESCENT HOME FOR SOLDIERS, TORQUAY.—At a special meeting of the subscribers to this institution held on May 31st it was reported that the subscriptions to the home had amounted to £3142 and the expenditure to £2581. As the convalescent home is now closed it was decided to hand the balance of £561 to the Soldiers and Sailors Help Society for the assistance of invalided soldiers belonging to Devon and Cornwall.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD

REPORTS OF MEDICAL OFFICERS OF HEALTH

Finsbury Urban District.—Dr George Newman furnishes in his current annual report a very interesting account of a milk borne outbreak of scarlet fever in which the milk responsible for the spread of the disease had come from a Staffordshire farm. The outbreak illustrates the difficulty of tracing food borne illness in London and shows how far afield the Londoner may have to look for the source of infection Referring to the deaths which occurred from phthisis during 1901 Dr Newman points out that they took place mainly in those houses which were overcrowded on area, were without sufficient open space and were of comparatively low rental. He has noticed the remarkable fact that under the above circumstances, but in localities which were in immediate proximity to open spaces, the deaths from phthisis have been few He finds, too, that a large number of cases have occurred in the same house—i.e., between 18 and 20 per cent. of these deaths took place in houses in which there were during the last six years two or more deaths from phthisis. Much of the report under review is devoted to the very important but too little attended to subject of the protection of our food-supply, and it is fortunate that the Extra Corporation meat market, which is the second largest dead meat market in London, has come beneath the control of a medical officer of health who evidently devotes much attention to our food supply In the matter of tuberculous meat the Finsbury Borough Council resolved despite Dr Koch's statement of opinion at the British Congress on Tuberculosis, "to continue to use all the powers at their disposal and to relax no effort whatever to protect the public against the spread of tuberculosis by milk and meat, and that the medical officer of health and inspectors continue to act as heretofore." The report now being dealt with also contains an account of the outbreak of illness due to cheese-poisoning which occurred in Finsbury in October, 1901. The symptoms in all the 17 cases began from two to eight hours after eating the cheese—a fact which, as Dr Newman states, points rather to poisoning by ptomaines already formed than by means of bacteria themselves, in which case a longer time would be likely to elapse between the consumption of the food and the onset of the symptoms. From the cheese in question the public analyst was able to isolate a body resembling the tyro-toxicon first isolated by Vaughan in America in 1883. It seems, too, that a similar outbreak occurred in Bermondsey in the autumn of 1901 as a consequence of the consumption of Dutch cheese, and cases were also reported from Deptford and Croydon. The cheeses involved were all eventually traced to one factory in Holland Although the outbreak was carefully worked out it cannot be said that much light has been thrown upon the subject, and it is not probable that we shall succeed in preventing occurrences of this nature until places where food is manufactured and prepared are placed under more adequate supervision than they are at present. Dr Newman evidently recognises this point, as he tells us that he made during 1901 inspections of sweetmeat and other factories and that attention has also been paid to restaurants, dining rooms, eating houses, &c. It is to be regretted that operations such as these are not more general. The necessity for some such supervision was accentuated in the recent report of the Departmental Committee on Food Preservatives and it would be well if its recommendations were acted upon.

Bournemouth Urban District—Mr P W G Nunn paid a visit during the year under review to certain oyster beds or ponds in Poole Harbour and he was accompanied by Mr F T Tanner, the borough bacteriologist They found the beds so situated that pollution by sewage was inevitable and the bacteriological examination of oysters procured from the source in question revealed the presence of sewage organisms in large numbers. Enteric fever was, it is alleged, traced to the consumption of oysters taken from this source. This is a most unsatisfactory condition of affairs more particularly as it is practically impossible to remedy it under the present law It is eminently desirable that there should be such legislation as will enable a county or other local authority to prevent the laying down of oysters near a sewer or drain outfall. Until this takes place there will always be some danger from the promiscuous consumption of oysters

Chesterfield Rural District—Dr Herbert Peck describes in his annual report the outbreak of epidemic jaundice which occurred in this district during 1901. It began in August and continued until the advent of the cold weather 69 cases were brought to the notice of the medical officer of health who thinks that the evidence pointed clearly to infection as a means of spread. There were multiple cases in several houses. As regards sex distribution there was a material preponderance in the male sex and the bulk of the attacks occurred in the age period from 26 to 30 years The illness appears to have had a gradual onset with vomiting, shivering, and some rise of temperature. The jaundice supervened about the third day of the illness Dr Peck states that the period of incubation was six or seven days and the duration of the malady about four days. The origin of the disease is still obscure albeit infectivity played a part in its spread

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 76 of the largest English towns 8182 births and 4569 deaths were registered during the week ending June 7th The annual rate of mortality in these towns, which had been 17·3, 16·7, and 16·5 per 1000 in the three preceding weeks, further declined to 16·0 per 1000 last week. In London the death rate was 14·9 per 1000, while it averaged 16·6 in the 75 other large towns. The lowest death rates in these towns were 6·6 in Handsworth, 7·6 in Hornsey 8·5 in East Ham, 8·8 in West Hartlepool, 9·8 in Newport (Mon.), 10·0 in Aston Manor, and 10·2 in Croydon and in Bournemouth, the highest rates were 22·9 in Sunderland 23·0 in Tynemouth, 23·1 in Gateshead, 24·3 in Preston 24·4 in Bootle, 24·5 in Oldham, 25·7 in Middlesbrough and 29·7 in Wigan The 4569 deaths in these towns last week included 555 which were referred to the principal zymotic diseases, against 516 531, and 505 in the three preceding weeks, of these 555 deaths 173 resulted from measles, 132 from whooping-cough, 59 from diphtheria, 55 from scarlet fever, 49 from small pox, 47 from diarrhœa, and 40 from "fever" (principally enteric) No death from any of these diseases was registered last week in Hornsey, Brighton, Northampton Devonport Handsworth, Stockport, York, or Newport (Mon), while the highest zymotic death rates were recorded in St Helens, Wigan, Barrow in-Furness, Sunderland Newcastle Tynemouth, and Rhondda. The greatest proportional mortality from measles occurred in Tottenham, Plymouth Wigan, Rochdale, Rhondda, Bradford, Stockton on Tees and Sunderland, from scarlet fever in Burnley and Middlesbrough, from diphtheria in Grimsby, Middlesbrough, and Rhondda, and from whooping-cough in Coventry, Wigan, Barrow in Furness, South Shields, Newcastle, and Tynemouth. The mortality from "fever" showed no marked excess in any of the large towns Of the 49 fatal cases of small pox registered last week 29 belonged to London, six to West Ham, five to Swansea, two to Willesden, two to Croydon, two to Tottenham two to East Ham, and one to South Shields The number of small pox patients under treatment in the Metropolitan Asylums hospitals which had been 1360, 1344 and 1274 at the end of the three preceding weeks, had further declined to 1162 at the end of last week, 188 new cases were admitted during the week, against 233, 307, and 251 in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital on Saturday, June 7th was 2314 against 2207 2236, and 2206 on the three preceding Saturdays, 310 new cases were admitted last week, against 270, 260 and 319 in the three preceding weeks The deaths referred to diseases of the respiratory organs in London, which had been 216, 237, and 261 in the three preceding weeks, declined again last week to 200, and were 20 below the average. The causes of 43, or 0·9 per cent, of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in West Ham, Bristol, Salford Newcastle-on Tyne, and in 48 other smaller towns, the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Rochdale, Bradford, Sheffield, Middlesbrough, and Sunderland.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·4, 20·3, and 19 3 per 1000 in the three preceding weeks, was again 19·3 per 1000 during the week ending June 7th, and showed an excess of 3·3 per 1000 over the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 10·6 in Leith and 15·4 in Dundee to 23·4 in Greenock and 27·5 in Paisley. The 623 deaths in these towns included 22 which were referred to measles, 16 to diarrhœa, 15 to whooping-cough, three to scarlet fever, three to diphtheria, and two to "fever." In all 61 deaths resulted from these principal zymotic diseases last week, against 55 and 57 in the two preceding weeks. These 61 deaths were equal to an annual rate of 1·9 per 1000, which corresponded with the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of measles, which had been 21, 16, and 13 in the three preceding weeks, rose again last week to 22, of which seven were registered in Glasgow, seven in Paisley, four in Edinburgh, and two in Dundee. The deaths from diarrhœa, which had been 14 and 15 in the two preceding weeks, further increased to 16 last week, and included six in Dundee, four in Glasgow, three in Aberdeen, and two in Edinburgh. The fatal cases of whooping-cough, which had been 14 and 22 in the two preceding weeks, declined again last week to 15, of which 13 occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 114, 156, and 129 in the three preceding weeks, further declined last week to 116, but were 18 in excess of the number in the corresponding period of last year. The causes of 17, or nearly 3 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 19·1 and 22·3 per 1000 in the two preceding weeks, declined again to 19 8 per 1000 during the week ending June 7th. During the past four weeks the death-rate has averaged 21·5 per 1000, the rates during the same period being 16·0 in London and 18·3 in Edinburgh. The 144 deaths of persons belonging to Dublin registered during the week under notice showed a decline of 18 from the number in the preceding week and included six which were referred to the principal zymotic diseases, against 13, six, and eight in the three preceding weeks; of these, three resulted from measles, and one each from scarlet fever, diphtheria, and whooping-cough. These six deaths were equal to an annual rate of 0 8 per 1000, the zymotic death-rates during the same period being 2·1 in London and 1·5 in Edinburgh. The fatal cases of measles, which had been three, two, and two in the three preceding weeks, rose again last week to three; the mortality both from scarlet fever and from whooping-cough corresponded with that shown in the preceding week, while that from diphtheria was slightly lower. The 144 deaths in Dublin last week included 30 of children under one year of age and 24 of persons aged upwards of 60 years; the deaths of infants were slightly below the number recorded in the preceding week, while those of elderly persons showed a very considerable decline. Eight inquest cases and six deaths from violence were registered; and 52, or more than a third, of the deaths occurred in public institutions. The causes of 10, or more than 7 per cent., of the deaths registered in Dublin last week were not certified.

VITAL STATISTICS OF LONDON DURING MAY, 1902.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in each of the cities and boroughs in the county of London. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 10·3 per 1000 of the population, estimated at 4,579,107 persons in the middle of the year. In the three preceding months the rates had been 11 4, 11·9, and 10·5 per 1000 respectively. The rates were considerably below the average in Paddington, Kensington, Hammersmith, St. Marylebone, Hampstead, and Stoke Newington, while they showed the largest excess in Bethnal Green, Stepney, Poplar, Southwark, Bermondsey, and Lewisham. The prevalence of small-pox last month showed a marked decline from that recorded in the preceding month of this year. The greatest proportional prevalence of this disease occurred in Bethnal Green, Stepney, Poplar, Southwark, Bermondsey, and Lewisham. The Metropolitan Asylums hospitals contained 1274 small-pox patients at the end of last month, against 1309, 1526, and 1442 at the end of the three preceding months; the weekly admissions averaged 260, against 390, 461, and 319 in the three preceding months. The prevalence of scarlet fever during the month under notice exceeded that recorded in any of the three preceding months; this disease was proportionally most prevalent in Hackney, Finsbury, Poplar, Camberwell, Deptford, and Lewisham. The number of scarlet fever patients under treatment in the Metropolitan Asylums hospitals, which had been 2250, 2113, and 2176 at the end of the three preceding months, had further risen to 2222 at the end of last month; the weekly admissions averaged 274, against 234, 258, and 258 in the three preceding months. Diphtheria showed a slightly increased prevalence during May as compared with that recorded in April; among the various metropolitan boroughs this disease was proportionally most prevalent in St. Pancras, Hackney, City of London, Stepney, Poplar, and Lewisham. There were 960 diphtheria patients under treatment in the Metropolitan Asylums hospitals at the end of last month, against 1154, 1123, and 1035, at the end of the three preceding months; the weekly admissions averaged 146, against 154, 156, and 140 in the three preceding months. The prevalence of enteric fever last month was slightly greater than in either of the two preceding months; the greatest proportional prevalence of this disease occurred in the City of Westminster, Shoreditch, Bethnal Green, Southwark, and Bermondsey. The number of enteric fever patients in the Metropolitan Asylums hospitals, which had been 142, 121, and 115 at the end of the three preceding months, had risen again to 127 on May 31st; the weekly admissions averaged 19, against 17 in each of the two preceding months. Erysipelas was proportionally most prevalent in Paddington, Holborn, Bethnal Green, Southwark, and Bermondsey. The 26 cases of puerperal fever notified during the month included four in Southwark and two each in Fulham, City of Westminster, Hackney, Stepney, Poplar, and Lewisam.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various metropolitan boroughs, the deaths occurring in public institutions having been distributed among the various boroughs in which the deceased persons had previously resided. During the four weeks ending May 31st the deaths of 5601 persons belonging to London were registered, equal to an annual rate of 15·9 per 1000, against 25·9, 20·4, and 16·8 per 1000 in the three preceding months. The lowest death-rates last month in the various metropolitan boroughs were 9·8 in Hampstead, 10·1 in Stoke Newington, 12·0 in Lewisham, 12·3 in Wandsworth, 13·1 in Paddington, and 13·9 in Hammersmith; while the highest rates were 19·3 in the City of London, 19·7 in Stepney, 20·4 in Bethnal Green, 20·9 in Holborn, 22·1 in Southwark, and 23 8 in Chelsea. The 5601 deaths from all causes included 153 from small-pox, 221 from measles, 42 from scarlet fever, 88 from diphtheria, 155 from whooping-cough, 23 from enteric fever, and 56 from diarrhœa; in all, 738 deaths were referred to these principal zymotic diseases. These 738 deaths were equal to an annual rate of 2·1 per 1000, the lowest death-rates from these zymotic diseases being recorded in Paddington, Kensington, City of Westminster, St. Marylebone, Stoke Newington, and Greenwich, and the highest rates in Chelsea, St. Pancras, Bethnal Green, Stepney, Poplar, and Southwark. The 153 fatal cases of small-pox were 100 less than the number in the preceding month; the greatest proportional mortality from this disease occurred in Hackney, Stepney, Poplar, Southwark, and Woolwich. The 221 deaths from measles showed a decline of 79 from the average number in the corresponding periods of the 10 preceding years; among the various metropolitan boroughs this disease was proportionally most fatal in Chelsea, Holborn, the City of London, Stepney, Southwark, and Battersea. The 42 fatal cases of scarlet fever were 17 below the corrected decennial average number; the greatest

* Including membranous croup.

proportional mortality from this disease was recorded in Kensington, City of Westminster, St. Pancras, Poplar, and Lambeth. The deaths from diphtheria last month numbered 88, against an average of 148 in the corresponding periods of the 10 preceding years. Among the various metropolitan boroughs this disease was proportionally most fatal in St. Pancras, Bethnal Green, Stepney, Poplar, and Lewisham. The 155 fatal cases of whooping-cough showed a decline of 40 from the corrected average number; the greatest proportional mortality from this disease occurred in Holborn, Bethnal Green, Stepney, Southwark, and Bermondsey. The 23 deaths referred to enteric fever were eight below the average number in the corresponding periods of the 10 preceding years; among the various metropolitan boroughs this disease was proportionally most fatal in Westminster, Islington, Stepney, Lambeth, and Battersea. The 56 fatal cases of diarrhœa were also slightly below the average; the highest death-rates from this disease were recorded in Paddington, Hammersmith, Finsbury, Shoreditch, Lambeth, Lewisham, and Woolwich. In conclusion, it may be stated that the aggregate mortality in London last month from the principal zymotic diseases was more than 7 per cent. below the average.

Infant mortality in London during May, measured by the proportion of deaths of children under one year of age to registered births, was equal to 117 per 1000. The lowest rates of infant mortality were recorded in Hampstead, St. Pancras, Stoke Newington, Wandsworth, and Lewisham; and the highest rates in Kensington, Chelsea, City of Westminster, Southwark, and Greenwich.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Deputy Inspector-General M. Fitzgerald to Haslar Hospital. Surgeons: A. K. Smith-Shand, W. N. L. Cherry, and E. L. R. Thomas to the *Duke of Wellington;* T. W. Miles to the *Wildfire;* J. Fullerton and J. G. Peebles to the *Pembroke;* L. M. Morris, O. Mills, and N. H. Mummery to the *Vivid;* and T. B. Shaw to the *Resolution.*

ROYAL ARMY MEDICAL CORPS.

Major Smith proceeds home from Sierra Leone on relief by Major Crofts.

Major B. M. Skinner is appointed Secretary to the Army Nursing Board in connexion with Queen Alexandra's Imperial Military Nursing Service. Captain O. O'C. Hodgens takes up duty at Dover.

Lieutenant-Colonel P. M. Ellis has arrived at Colchester.

ROYAL ARMY MEDICAL CORPS (MILITIA).

The undermentioned officers are seconded for service in South Africa:—Lieutenant G. J. D. Davies and Lieutenant S. G. McAllum.

VOLUNTEER CORPS.

Royal Engineers (Volunteers): 2nd West Riding of Yorkshire (Leeds): William Hearfield Galloway, to be Surgeon-Lieutenant.

Rifle: 1st (Exeter and South Devon) Volunteer Battalion the Devonshire Regiment: John Shirley Steele Perkins to be Surgeon-Lieutenant. 22nd Middlesex (Central London Rangers): Surgeon-Lieutenant A. Ehrmann to be Surgeon-Captain. 1st Tower Hamlets: Surgeon-Lieutenant O. A. Marrett to be Surgeon-Captain.

VOLUNTEER INFANTRY BRIGADE BEARER COMPANIES.

Devon: Surgeon-Lieutenant H. W. Webber, from 2nd Devonshire Royal Garrison Artillery (Volunteers), to be Surgeon-Lieutenant, and to command under paragraph 55A Volunteer Regulations. North East Lancashire: Surgeon-Captain J. M. H. Martin, from 1st Volunteer Battalion East Lancashire Regiment, to be Surgeon-Captain, and to command under paragraph 55A Volunteer Regulations; Surgeon-Captain T. Holt, from 2nd Volunteer Battalion the East Lancashire Regiment, to be Surgeon-Captain.

THE LOSSES IN THE LATE WAR.

The total reduction of the military forces through the war in South Africa up to the end of May last, according to the last monthly return published by the War Office, is stated to have been 28,434, which includes 1080 officers and 27,354 non-commissioned officers and men. Among those sent home as invalids the great majority have recovered and rejoined for duty. According to the statement of Lord Stanley on June 9th, in reply to a question in the House of Commons, the number of soldiers who, having been discharged as medically unfit for further service on account of disability during the South African war, have been awarded pensions is 14,398; the number of widows and children of soldiers who have died in the war, to whom pensions have been awarded is: widows, 2863; and children, 4184. It is not possible, of course, to give any estimate of the number of future recipients of such grants.

VOLUNTEER MEDICAL ASSOCIATION.

The annual challenge shield competition was held at the Guildhall, London, on June 7th, when the proceedings were witnessed by a large number of volunteer medical officers and ladies, including a contingent of the St. John Ambulance nursing sisters. The following are the names of the competing teams in the order of merit:—The 5th (Glasgow Highland) Volunteer Battalion the Highland Light Infantry; the 3rd Volunteer Battalion the Queen's Royal West Surrey Regiment; the 1st City of London Rifle Brigade; the 21st Middlesex (Finsbury) Volunteer Rifle Corps; the 1st Cadet Battalion the King's Royal Rifles; the 2nd Volunteer Battalion Royal Fusiliers (City of London Regiment); the 1st Volunteer Battalion the Princess of Wales's Own Yorkshire Regiment; the 4th Durham Royal Garrison Artillery (Volunteers); and the 2nd Volunteer Battalion the Essex Regiment.

IMPERIAL YEOMANRY HOSPITALS.

The anniversary dinner to commemorate the capture of the Imperial Yeomanry Field Hospital and Bearer Company at the battle of Roodewal was held at the Criterion Restaurant on Saturday last. Major Stonham, C.M.G., presided, and there were present upwards of 90 members of all ranks of the company.

PAY OF THE ROYAL ARMY MEDICAL CORPS IN INDIA.

The Secretary of State for India has decided to approve an increase to the pay of officers of the Royal Army Medical Corps below the rank of Major while serving in India, and also the issue of charge allowances for senior medical officers of station hospitals in that country.

Correspondence.

"Audi alteram partem."

HOSPITAL SUNDAY.

To the Editors of THE LANCET.

SIRS,—Sunday next is the thirtieth anniversary of the institution of "Hospital Sunday" in the metropolis, and collections will then be made in every place of worship in the vast area of London in aid of the hospitals, dispensaries, and convalescent homes which do so much for the alleviation of the necessities of the suffering poor.

The rapid increase in the population of London intensifies the need for these beneficent institutions, but unfortunately the subscriptions do not sufficiently keep pace with the requirements. Thus the largest and wealthiest city in the world, and the capital of the British Empire, labours under serious disadvantage in dealing with its sick population.

To help to remedy this state of affairs it is necessary for at least £100,000 to be raised by next Sunday's offertories. Mr. George Herring, who has contributed large amounts in previous years, has now offered either to add one-fourth to the amount raised on Hospital Sunday by the various places of worship, or to give a donation of £10,000.

The Council decided to accept the former offer, believing that it would stimulate other donors. With this munificent proposal it is surely not hopeless to expect to raise the desired sum of £100,000.

The Hospital Sunday Fund neither clashes nor competes with any other organisation except in the friendliest rivalry, and it is hoped that this historic year may be rendered memorable in its annals by an unprecedentedly large collection in aid of His Majesty's suffering poor in London.

Those who may be away from London, or unable to attend houses in the borough of Godalming which drained into the river Wey above the mills there were some cases of typhoid fever in April and May; the specific poison of the fever, therefore, was probably passing into the river from that house at the time when it was distributed to the cisterns in the clay-room at the mills." (*Public Health*, vol. iv., p. 188.)

An outbreak of typhoid fever at King's Lynn and Gaywood (Norfolk) was reported on in 1892 by Dr. Bruce Low. This outbreak was particularly interesting because it was ushered in by a "sudden outbreak of diarrhœa attacking all classes and all parts of the town during the last few days in February, followed by development of numerous typhoid cases about a fortnight later." This outbreak was due to the fact that the water-supply of the town was derived from Gaywood river which flows through cultivated fields and gardens. The intake of the water is within the borough boundary and the filtration adopted is very insufficient. The contents of privy pits in the town into which the discharges of some typhoid fever cases have been thrown were spread before the time of the outbreak on part of a market garden abutting on the river and about a mile above the intake of the water-supply and the "excreta from a house outside Gaywood wherein eight persons were attacked one after the other with typhoid fever between November and March had been placed in a pit in the garden, from which it was washed into the river above the intake by the melted snow and heavy rainfall that occurred in the third week in February."

Dr. Bruce Low reported in 1893 on an outbreak at the villages of Nunnington and Ness-in-Ryedale (Yorks). The water-supply of these villages is derived from the river Rye which is largely polluted by the sewage of Helmsley and by the washings from land on which local privy "muck" and Leeds town manure are spread from time to time The chief interest in this outbreak is that it was cut short by all the water used for all domestic purposes being boiled. In 1895 Dr. Bruce Low reported on an outbreak of typhoid fever in September in certain riverside villages below Helmsley, just after the outbreak at that town caused by infected milk (see page 1022). This outbreak was "confined to those persons who drank raw river water taken from the Rye at points below that at which it is polluted by the sewage of Helmsley."

In 1897 Dr. F. St. G. Mivart reported on a sudden outbreak of typhoid fever at King's Lynn borough and Gaywood parish (Norfolk) early in October. The fever was distributed indifferently throughout both places. The water-supply was derived from the river Gaywood "which is exposed freely to pollution of all kinds throughout its course." The river water was delivered without filtration, an abundance of contaminating matters having been washed into the river by the excessive rainfall on Sept. 29th.

In 1899 Dr. S. W. Wheaton reported on an outbreak in the borough of Ilkeston (Derbyshire) as follows: "Fever prevalence in all probability due to pollution of the general water-supply of the town, which is derived from the Nut brook and imperfectly filtered. The water of the Nut brook is grossly polluted by liquid refuse from dwellings at Henor, effluent from the Henor sewage farm, and numerous other sources of contamination."

In the twenty-second annual report of the State Board of Massachussets for 1890 is a report on typhoid fever in its relation to water-supply by Mr. Hiram F. Mills, in which it is stated: "Twenty-five years ago the average number of deaths by typhoid fever in 10,000 inhabitants in the places which are now cities in this State was 7 8, the number now dying yearly from this disease in the same places is 4 6 in 10,000 inhabitants. In fact, the actual number of deaths from this disease 25 years ago in these places, when their population was only six-tenths as much as at present was as great as it is now, and if measures for its prevention had not been taken and the death-rate had continued as it was 25 years ago we should now have 1000 deaths yearly, when the actual number in the cities is about 600. By carefully plotting upon maps of the cities the residence of all cases reported to the local Board of Health, together with the deaths, the distribution, though not even over the whole city nor strictly proportioned to the density of population, was so general that it could not be attributed to possible cases of typhoid fever at two or three of the large number of farms that supplied milk to the 100 or 200 milkmen who distributed milk through the territory where the cases of disease were found. On the other hand, the cases found in Lawrence were all within the territory supplied with water from the city waterworks, and several of the cases were in the thinly settled and apparently very healthy portions of the city, near the outer limits of the water-pipes. In Lowell the cases were very generally distributed throughout the territory, the numbers following nearly the density of the population. These conditions and the discovery of a probable cause of the contamination of the Lowell water-supply by fæces of typhoid patients discharged into Stony Brook, only three miles up stream from the intake of the Lowell waterworks, followed in a few weeks by the very rapid increase in the number of deaths from typhoid fever in Lowell, and these deaths followed in about six weeks by an alarming increase in the number of deaths in Lawrence, whose water-supply is drawn from the Merrimack river nine miles down stream from where the Lowell sewage enters the river, and the further discovery in December of typhoid fever germs in water from the service-pipes of the city of Lawrence, induced the board to send to the Mayor of Lawrence" a letter "warning the citizens not to use the city water for drinking until after it has been boiled for at least 15 minutes; and that when boiled it should not be cooled by putting into it ice obtained from the river this winter. This precaution should be continued as long as typhoid fever prevails in Lowell."

And he sums up the results of his investigation as follows: "We have found this relation existing between typhoid fever and water-supply—viz., that in general in the cities of the State the death-rate by typhoid fever has been greatly reduced by the introduction of a pure public water-supply; that in the one city, where there has not been such a reduction, a portion of the people use for drinking water from canals or from wells subjected to serious pollution by sewage; and that the deaths from this disease are much more frequent among that portion of the community than among others. The only two remaining cities which have not decreased death-rates by typhoid fever after the introduction of public water-supplies receive their supplies from a river polluted by sewage; and the seasons in which this disease prevails in these cities are later than those of other cities, and in the lower city on the river later than in the upper city, at a season when other cities are nearly free from the disease and at the time when it would follow if produced by the sewage from the upper city; further, that when the water of the river which passed the upper city and received its sewage during the greatest prevalence of the disease there had reached the service-pipes of the lower city, and there was the greatest prevalence of the disease in the lower city, typhoid fever germs were found in water from these service-pipes."

In the twenty-fourth volume of the reports and papers of the American Public Health Association for 1898 an account is given by Dr. John Leal, health officer, Paterson, New Jersey, of an outbreak of which he says: "No possible common means of infection could be found except the public water-supply, upon which all of those affected, with the possible exception of two or three, were dependent for at least a portion of the 24 hours. It also appeared that the only section of the city which did not contain a single case of the disease was also the only section not furnished with the public water-supply." It appears that "a resident of Little Falls (a place on the river above Madison) returned from a summer resort ill with typhoid fever on August 28th. The fever subsided about Oct. 1st but a relapse followed, lasting from about Oct. 8th to the end of the month, when finally convalescence began. The water-closet receiving the discharges of the patient was connected with a series of cesspools, connected with each other by overflow-pipes, and the last cesspool of the series discharged through a hidden pipe into the river. These cesspools, having thus become infected about Sept. 1st, continued to receive fresh infection until about Nov. 1st, when the patient was actually convalescent." Bacteriological examination of the water above Little Falls gave a negative result both as to bacillus coli and bacillus typhosus, but "below Little Falls the chemical evidence of harmful pollution was found, the average number of bacilli per cubic centimetre was 600, and in 90 per cent. of the specimens examined colonies of the common colon bacillus appeared." On a specimen taken at the intake on Sept. 23rd Dr. Connolly reported as follows: "Tests for typhoid bacilli revealed the presence of a non-liquefying active-motile bacillus which did not produce gas in the presence of culture media containing sugar, nor did it produce indol, and in other respects was identical with the typical bacillus of typhoid fever."

their accustomed place of worship, are invited to send their contributions direct to me at the Mansion House.

I am, Sirs, your obedient servant,
JOSEPH C. DIMSDALE, Lord Mayor
The Mansion House, London, E C., June 11th, 1902.

PAYING WARDS AND PAYING HOSPITALS.

To the Editors of THE LANCET.

SIRS,—Will you kindly lend me a little of your valuable space to congratulate Dr R. Saundby and Mr. B. W Housman on their excellent letters in THE LANCET of May 10th, p. 1356. They show, in both cases, a proper grasp of the situation and they proceed on lines of real reform in the best interests of all classes of medical practitioners. Our profession, like all other professions, must live; and, as society is now constituted, it ought to be paid for its labours on a proper financial basis. The time is past for medical men to lay the burthen of paying for the poor entirely upon the rich With civilisation advancing and wages increasing money has become the universal medium of exchange. Each class is getting more and more independent of other classes and must stand on its own feet in the different relations of life, and so it has come about that charity to the working class is unnecessary and uncalled for, and the doctor has to manage his professional work as all other professions have to manage theirs, on true business lines all round. The ideal state of matters, then, would be that we medical men should be paid on a fitting scale for every form of work done, whether in a hospital or club, or any other *quasi*-benevolent institution, and that the charitable element, so far as our duties are concerned, should be entirely eliminated. I need scarcely add that practically such a dream cannot be realised *per saltum*. So complete a change in our relations with the public must, we know, take a long time to effect. *Above all, we ourselves must learn to combine* Looking at matters not only as they affect us, but as they react on the public at large, if time and your space were available it could be clearly shown that such a reform would encourage on the part of our people the best of all qualities in the wear and tear of life—good, honest independence. It is because there is so much of this spirit in the letters I have referred to that I welcome them as I do.

Dr Saundby, having scored a victory over the ill-considered and impracticable, if well intentioned, scheme of the Birmingham Consultative Institute, has shown much good sense and magnanimity in recognising what was really valuable and sure ultimately to emerge from that conception. He very properly argues for taking time by the forelock and invites the opinions of others on the principles which should regulate a self-supporting scheme of paying hospitals open to the better-paid working man and to lower middle-class patients.

Having bestowed some time and attention on the consideration of this subject I venture to suggest certain propositions—not by any means as if I considered them as proved to the satisfaction of everybody but as the basis of further discussion of the subject. The first proposition I would venture to advance is that the scheme should be worked on coöperative principles on both sides Every person, without distinction as to wages, salary, or otherwise, should be able if he chose to avail himself of such an institution and every regular consultant, medical, surgical, or specialist, should be, if he or she chose, on the list of the recognised staff. Secondly, board, lodging, and nursing should be fixed at a moderate rate, while the fee for medical and surgical attendance should be left to the particular physician or surgeon in attendance. Thirdly, a list of physicians, surgeons, and specialists, with their fees, should be posted up in the hospital, patients being at liberty to select their own doctor. Consultations would be arranged for on similar lines.

In order to start such a hospital sufficient funds would require to be guaranteed. After a time the institution would have to be self supporting The friends of the working men and the working men themselves would have to be convinced of the wisdom of the scheme and agree heartily to help it in every way so as to make it successful. As to management a joint board of management should be formed, of which the medical element would have to constitute a full half and the representatives of the classes to be benefited the other half. The bargain must be a fair one between those who are giving their services and those who are accepting the same, both parties meeting on equal terms. The establishment would be run on strictly business lines. One objection to the scheme suggested which occurs to me is that there might be a press of cases waiting to be admitted and consequent grumbling on the part of those members of the staff who failed to get their patients into the hospital. The remedy would naturally be the provision of more beds and the hospital might be originally built on a plan which would readily admit of extension, and there would be no reason why another hospital might not be set up if the first one became, so to speak, too successful.

It will be seen that I have said nothing as to limiting those admitted so as to exclude the rich. I do not believe in any such tests They are too inquisitorial and invidious to work well. But I would be in favour of getting as many as possible subscribers of 6*d*. weekly with a preferential right to admission and that on a reduced scale. This plan of itself would naturally limit the class of applicants and if the contributors were numerous would provide for a more certain and steady income at all times and seasons than if the scheme depended merely on the number of beds occupied.

One word in conclusion in favour of paying hospitals As things are constituted at present patients with only moderate means must choose between expensive nursing homes and large fees and hospitals with no charge of any kind. Who can doubt that most prefer the latter alternative, and in this way the profession as a body (and I should think more particularly operating surgeons) lose very heavily! Surely, here the middle course is best and I believe that a *via media* will most easily be found by adopting some such plan as I have attempted all too ineffectively to sketch. I have left myself no room to deal with Mr. Housman's suggestions But I hope, with your leave, to take them up by and-by I believe the principles I have tried to enunciate would equally well apply to clubs and club doctors.

I am, Sirs, yours faithfully,
WILLIAM BRUCE.
May 27th, 1902.

ON THE USE OF THE TERM "BLASTOMA."

To the Editors of THE LANCET

SIRS,—In THE LANCET of May 31st (p. 1562) there is a letter from Professor Adami criticising my use of the term "blastoma." I must confess that I was not aware of the fact that the term had been used by Professor Klebs and I must thank Professor Adami for calling my attention to it Since reading his letter I have referred to Klebs's work ("Allgemeine Pathologie") and I find that Professor Adami's description of Klebs's classification is not quite accurate. Klebs uses the term "blastomata" as a synonym for "true tumours," but he includes under this term many conditions which are not considered tumours at the present day. He divides the blastomata or true tumours into *three* primary classes. The first class he calls "typical blastomata" and uses the synonym "giant growths" (*riesenwuchse*) They are those conditions which I called progressive hypertrophy The second class is that of the "atypical blastomata" and includes all the ordinary tumours and also tubercle, leprosy, &c. The third primary class is that of the "teratoblastomata" or "teratomata" which, besides dermoid cysts, &c., includes tumours arising from fœtal remains, such as those originating in branchial clefts, &c. Thus the term "blastoma," as used by Klebs, includes all tumours, progressive hypertrophies, and tubercle, leprosy, &c. I think that no one at the present day would defend this use of the term.

Professor Adami uses the term to designate the ordinary tumours as opposed to the teratomata—a use different to that of Klebs. Professor Adami's classification[1] is one rather of the antecedents of tumour formation than of tumours themselves. As a classification of tumours it is useless owing to the overlapping of the different subdivisions. Carcinoma, for instance, would occur in all the subdivisions of his group "blastomata." He draws too sharp and artificial a line between the teratomata and other tumours. He defines the blastomata as "tumours composed of the products of aberrant growth of cells and tissues of the individual in whom they develop," and the teratomata as "tumours composed of the products of growth of one individual within the tissues of another individual of the same species." He states that ovarian and testicular dermoids probably arise from the germ cells, and he therefore includes them in the teratomata, but what about dermoids in other situations? Are they, then, blastomata, or do they arise from wandering germ cells? Can Professor Adami tell us at what point an ovarian ovum ceases to belong to the ovary and becomes a separate individual? Again, in the case of transplantation of tumours from one animal to another does a tumour which is a blastoma in the first animal become a teratoma in the second. I do not think that any single term is necessary to designate collectively the ordinary tumours as distinct from the teratomata, and, if it were, the term "blastoma" would not be suitable since this meaning is not implied in it.

---

[1] The Causation of Cancerous and other New Growths, Brit. Med Jour., 1901, vol. i., March, 16th.

The tumours to which I have applied the term "blastoma" are best illustrated by the congenital mixed tumours of the kidney and many parotid growths. These tumours are neither sarcomata nor carcinomata in the accepted meanings of these terms. The fundamental cells of these growths are indifferent cells, and as proliferation proceeds some of them become differentiated into epithelial cells and others into the various forms of connective tissue cells and sometimes into muscle cells.

Now, Sirs, in the terms "fibroblast," "erythroblast," &c., the termination *-blast* signifies that the cells to which these terms are applied are immature. The term "blast" (βλαστός, germ) without any prefix would naturally signify an undifferentiated cell—that is, one which is not the precursor of any definite kind of cell but which may become differentiated into any kind of mature cell. We have also the old term "blastema" which was used to designate the undifferentiated substance from which the cells were supposed to be formed. The natural meaning, therefore, of the term "blastoma" is a tumour the essential components of which are undifferentiated cells and it is in this sense that I have used it, and I think that both by derivation and by analogy with cognate words I am justified in so using it.

In conclusion I must apologise to Professor Adami for not having, through an oversight, referred in my lectures to his use of the term "blastoma."

I am, Sirs, yours faithfully,
CHARLES POWELL WHITE.
Medical School, Leeds, June 9th, 1902.

OBSERVATIONS ON DIET.

To the Editors of THE LANCET.

SIRS,—"When doctors disagree," &c. Here is a point in question and in emphatic contrast. Dr. Harry Campbell, in a highly theoretic and erudite contribution to your pages,[1] says: "I cannot too emphatically impress upon my readers the desirability—nay, the necessity—of keeping the aged on a spare diet. Do not let us extinguish the flickering fire of age by piling on too much fuel." With your kind permission I have the honour to join issue here with Dr. Harry Campbell in no uncertain terms. Speaking from actual practical experience with many cases I should be inclined to be equally emphatic but would substitute the word "full" for the word "spare" and the word "withholding" for the words "piling on" in the above quotation. Many of the reasons advanced by Dr. Campbell I personally regard as indications for the exact reverse in the treatment. The only modifications experience has led me to introduce into the above are the words "suitably prepared full diet."

In the *British Medical Journal* of Oct. 13th, 1900, is published a paper by myself on the Dietetic Treatment of Cardiac Failure in the Aged, based on a matured practical experience of full feeding of aged persons, and inasmuch as heart failure is the main cause of death in the aged (lung and kidney diseases not being excluded) and a full diet having been found in my hands far and away more satisfactory than the reverse, I may be excused for appearing over enthusiastic and dogmatic on this matter. So much does my own experience (I cannot speak of the experience of others) force me to a contrary opinion to that expressed by Dr. Campbell that I have now come to look at the word "metabolism" as a veritable pitfall for those who have the care of an aged and failing patient. Rather "meta(dia)-bolism" *of starvation than* "*diet*"—*secundum artem* where the aged are concerned. "Lived in spite of them all" is often the grim chuckle of the wilful, disobedient aged person who has transgressed repeatedly and constantly "laid-down diet on restricted lines."

It is quite time we as a profession began to revise our practice and preconceived notions in certain directions where diet is concerned, and as an ounce of practice is worth a pound of theory, here goes. Of the cases quoted by me in the afore-mentioned paper every one is at present alive and well, after periods ranging from three to seven years, living on the fat of the land now, where previously they sank rapidly to dissolution on moderate diet. To these have since been added many others quite as, if not more, striking illustrations of the success of the reverse of a "spare diet." I feel confident that were it possible to take ten aged persons (cardiac, lung, and kidney complications included)—not ten healthy aged persons, but ten downright "broken-downs," typical "foot-in-the-grave" old people—and to place five on an anti-anything-one likes "spare diet" and the other five on a generous, good, full diet (not omitting the provision of false teeth), the whole of the spare diet seniles would be dead and gone before two (any two) of the full-fed seniles had succumbed. *Verb. sap.*, but *cui bono?*

I am, Sirs, yours truly,
June 9th, 1902. F. W. FORBES ROSS, M.D. Edin.

---

[1] THE LANCET, May 31st, 1902, p. 1554.

THE ROYAL NAVY MEDICAL SERVICE AND THE ROYAL ARMY MEDICAL CORPS: A COMPARATIVE VIEW.

To the Editors of THE LANCET.

SIRS,—As you have done me the honour in THE LANCET of June 7th, not alone of publishing my letter with the above heading (p. 1645), but also of commenting upon it in an annotation (p. 1613), may I be allowed to reply to some points raised in the latter. I shall not trouble you again, the time involved in the necessary searching through intricate regulations is too much for me to spare, and but for the kindly assistance of a retired naval officer would have compelled me to silence on the present occasion. Your annotator implies that my comparison is "partial, incomplete, and misleading." I hope to show that this is not so and that to some extent the latter term may be fairly retorted on him in regard to certain omissions he has made. Let me begin, as he does, with the question of allowances and take them as applying to a Staff Surgeon, R.N., and a Major R.A.M.C., each of 12 years' service. As your annotator states, the former has a furnished cabin and a servant, but he omits to state that he has to pay rent for the furniture of the former and wages to the latter; he has, as stated, a mess which costs him 2*s.* per day, but this is for food only, I am told, and takes no account of other mess subscriptions and all this has to come out of his pay of £438 per annum, whereas the Major R.A.M.C., in addition to his pay of £430 per annum, has allowances (*vide* Appendix to New Warrant) of £157 12*s.* 10*d.* with which to meet the same expenses, his pay being left intact apparently. Wherefore I venture to doubt your annotator's confident statement that the army man cannot live as well with his allowances as the navy man can without them. He must be poor at getting an equivalent for his money if he cannot. On the general question of these allowances I would like to refer your annotator, as I have been referred, to a letter by Mr. James Cantlie in the *British Medical Journal* of May 10th, p. 1182.

Now to take up your annotator's remarks on the points I raised. 1. Surely it is not the intention of those drafting new regulations for the King's service to insert words which "can be safely ignored." 2. It is a fact that there are officers now on the staff surgeons' list "with but four or five years' service as surgeons," but your annotator omits to state that these early promotions have been for war service (*vide* Lean's Royal Navy List), and these are not unknown in the Army Medical Service. But all this is entirely beside the question raised in paragraph 2 of my letter which referred to promotion by examination. 4. The hospital allowances mentioned as given to naval doctors when so serving are said to be in "lieu of provisions for themselves and their servants and for fuel and light." I am *told* that in England they are £53 for a fleet surgeon or a staff surgeon, and that it is only abroad they reach the higher figures named, and surely they should be compared with the army doctor's allowances for the same sort of thing and not with his charge-pay for being in charge of beds—a very different thing. 5. Your annotator's statement that this applies to all naval officers does but emphasise the truth of my comparison, by extending the area of its application. The consolation to be derived by A from seeing B in the same hole as himself while he sees C and D are out of it is a very remote one. 6 The army warrant provides specialist's pay in many other subjects than the solitary one of sanitation.

Trusting to your courtesy to insert this rejoinder,

I am, Sirs, yours faithfully,

June 9th, 1902. PARENT.

SANITATION AT THE DÜSSELDORF EXHIBITION.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

ACCORDING to official announcements the Düsseldorf Exhibition is the most important yet held in Germany Nevertheless, it is confined to the manufactures, industries, and art of the Rhine provinces, but these are of the very first importance. They illustrate the enormous progress achieved in Germany of late years and testify to an economic evolution which is of necessity attended by many grave social and sanitary problems. Consequently, of the 23 sections into which the exhibition is divided the twenty-first section, organised under the direction of Dr. Aug. Hoffmann, is devoted to "sanitary arrangements and social institutions." But questions affecting public health arise in other sections and notably in the very elaborate exhibitions illustrating the mining industries. At the same time it must be recognised at once that though this is essentially a technical exhibition it is only incidentally that matters dealing with the technicalities of medical and sanitary science may be studied. But Düsseldorf is within half an hour's journey from Cologne—a town where so many travellers stop on their way to the Rhine, Switzerland, Germany, and the East. Then and apart from the exhibition Düsseldorf is a beautiful town, well worth a visit. The ornamental waters, the parks, the majestic trees, the verdant avenues, situated not on the outskirts, but in the very centre of the town, constitute a most remarkable and attractive feature of this great German centre of art and industry. Then the town seems to be well drained, very clean, and skilfully administered. The service of electric tramways is one of the most perfectly organised of any town in Europe and there can be no doubt that all who are interested in the technique of urban administration will find useful indications at Düsseldorf. On the other hand, the mere pleasure-seeker will rapidly exhaust the few attractions that have been provided. The exhibition is intensely technical and it is not given to the ordinary tourist to appreciate the functions of blast furnaces or the engineering difficulties of iron bridges that span the deepest stretches of the Rhine. The extensive Krupp exhibits and those of rival manufacturers in the production of modern engines of destruction and defence are of sinister, though of more general, interest, but in any case the magnificent art gallery with its numerous paintings will prove attractive to all.

Leaving, however, all these topics to those whom they especially concern, I will briefly mention what may interest those who study public health questions. Following the monumental Rhine embankment to the Rheinthor entrance of the exhibition the visitor will see immediately on the right a wooden lazaret or barrack and other portable structures. These are put up by the Deutsche Barackenbau Gesellschaft on the Brümmer system. This system is based on the principle that every separate piece of the building shall be of the same size and these shall be joined together in the same manner Consequently the building can be made large or small or reduced in size or enlarged according to varying requirements. Also, if a window is in an unsuitable position it is only necessary to unscrew that portion of the wooden wall which contains the window and to carry it elsewhere. Here the portion of the wall which has no window is in its turn unscrewed and exchanged for the portion of the wall which has a window. A good-sized barrack hut can be put up in about 24 hours, and if it does not occupy a surface of less than 100 square metres it will only cost £2 per square metre. For a quarantine station that has to be hastily constructed or for an isolation hospital this is, in any case, a ready and cheap contrivance. The manager, whom I questioned, assured me that these huts were strong enough to resist a hurricane.

A few steps further there is a pavilion mainly devoted to the exhibition of gigantic kitchen ranges and other domestic objects. Here Herr A. Ballauff shows some closets, baths, &c., which are in keeping with modern sanitary exigencies and the fittings for soap and sponges are thoughtfully devised. Then there is a new system of removeable handles for heavy tailoring and laundry irons and a closed stove for warming them By reducing the risk of burns and the escape of fumes these contrivances will be of service in many workshops. The greater part of the kitchen pots and pans, which in England would be black, more or less covered with soot, and treated as useful but not as æsthetic articles, are here enamelled and elaborately decorated with designs representing various flowers, &c. The kitcheners also are very delicately ornamented. Some are of a creamy white colour, with subdued tints and flowers in the centre. They suggest kitchens wonderfully free from smoke, soot, and dirt. There can be no doubt that the converting of kitchen utensils into works of art must tend to encourage cleanliness in the kitchen, and this must contribute to preserve the purity of the food, thus very materially benefiting the health of all concerned.

On the left-hand side of the Rheinthor and close by the banks of this noble river there is a row of workmen's model cottages. These have in many cases the advantage of being picturesque and varied in design. One of these houses is exhibited by the workmen's building societies of Remscheid, a centre of the cutlery and metal working industries where a great deal has been done to improve the condition of the working classes In this workman's dwelling artistic furniture is exhibited, and as the price is fixed to each article the object is to show that art is not necessarily expensive or beyond the reach of the ordinary artisan. Thus a really handsome and ornamental wooden bedstead costs 34s., a large wardrobe with double doors 66s., and so forth. The tidiness of the kitchen arrangements is remarkable. For instance, an enamelled slab is suspended to the wall near the kitchener on which the spoons, &c., used in the kitchen are hung up. The lower part protrudes so as to catch the drops that fall from the spoons or ladles and thus prevents grease spots on the floor. The side walls as well as the roof of this house are all covered with slates. Doubtless in a very rainy climate this must keep the interior dry. Other cottages close by showed very evident proofs of dampness inside; in many cases the wall-paper was absolutely discoloured.

The Arbeiterwohnungsgenossenschaft, Köln Süd also seeks to apply new art to workmen's furniture in a practical and economical manner Thus instead of one large wardrobe two smaller ones are placed at the head of the double-sized bed with a little shelf protruding to form a bed table to hold a watch, a candle, &c. Each wardrobe, therefore, serves a double purpose. The wood is painted and polished a dark green seaweed colour. A very choice dark-blue repp for the upholstering of the furniture matches the painting of the wood and harmonises with variegated yellow art muslins that are used wherever drapery is required. The kitchener is artistically enamelled and ornamented with flowers of subdued tones and costs 85 marks. The sitting- or drawing-room might be described as "a melody in brown," yet the entire cost of the furniture including a small bed is only 318 marks. The furnishing of the entire house suitable for a man and wife and an adult child or lodger costs £40. The kitchen measures 13·50 cubic metres and the two other rooms 18·50 and 13·50 cubic metres respectively; and the cost of building is 110 marks, or shillings, per square metre of surface. There can be no doubt that if workmen could be induced to live in such artistic homes cleanliness and tidiness would be the natural consequence, and this would contribute to maintain their health Thus art and sanitary science may well be considered as natural allies. Nor is this only an ideal conception The fact that such furniture is made and that the manufacturers have gone to the expense of exhibiting it shows that there is a demand among the working classes of Germany for such articles; though, of course, this is as yet exceptional.

On the other hand, the workman's cottage built by the Rheydter Actien-Baugesellschaft furnishes three rooms in a simple and ordinary manner and there is no attempt to introduce the teaching of the new art school. Yet this furniture, also for three rooms, costs £36, so that it is not much cheaper. The workman's cottage, as built at Essen-Ruhr for the workmen of the Krupp factory, is also simple and solid. This house looks thoroughly habitable and in the kitchen there is a wonderful store cupboard for provisions, &c., but the centre opens out and forms a writing-desk, with pigeonholes for account books, cookery books, bills, and receipts. If this does not suggest high art it certainly implies great and systematic economy and order. It would be difficult to conceive a spendthrift, slatternly housewife possessing such a piece of furniture. The chief defect in these exhibits of workmen's dwellings is the fact that no indication is given as to the method which it is proposed to employ to effect their drainage. The places for the sink and the closets are there, but nothing shows how it is proposed to flush, trap, and disconnect these services, nor are there any bathrooms provided, though an installation for a douche is shown in one of the cottages. Again, I failed to detect any trace of damp-proof course for the walls. On the contrary, the damp was very perceptibly spoiling the wall-papers and this without any let or hindrance. In quite another part of the grounds the directors of the Gelsenkirschen steel and ironworks exhibit two pretty double dwellings similar to the cottages which this company builds for its workmen. There is little or no art here, in regard at least to the furniture, and what can be seen of the drainage is not promising, for though the sink-pipe passes through the wall it gives into the rainwater spout and there is no interception. With regard to the technique of domestic drainage none of these German workmen's dwellings can compare with the installations of the "Sunlight" cottages exhibited at the Vincennes *annexe* of the Paris Exhibition in 1900.

The mining associations of Germany have quite a palace to themselves at the Düsseldorf exhibition, surmounted by a dome 130 feet high. Here much of what is done—or, perhaps in some cases it would be more correct to say what should be done—to protect life in the mining industries is exhibited. Indeed, what with the show uniforms which the miners wear—for in Germany even pitmen have uniforms—the elaborate system for giving warm douches when the men leave off work, the beautiful offices at the pit brow, the surgery with its aseptic fittings, the extensive machinery for ventilating the mine, and the underground galleries clean swept as if they were fashionable boulevards, it would really seem as if coal-getting was a most cleanly and agreeable occupation. Nobody perhaps is more surprised when they see all this than the working miner himself. In any case the picture thus presented shows what can and what should be done. It is not, therefore, without its useful purpose. There are among other life-saving contrivances sections of pit galleries fitted with large air-tight metal doors which on being closed can stop the circulation of dangerous gases. Then there is the breathing apparatus provided for the use of rescue parties when they venture in the midst of choke-damp, and, of course, many varieties of safety lamps are shown. There is also a pretty model of the Workmen's Colony Society which has built semi-detached cottages surrounded by large gardens where 470 miners' families live at Niederevving, near Dortmund. The coquettish appearance of these cottages and gardens is certainly a great improvement upon the ordinary mining villages to be seen in England.

The Social Economy and Hygiene Section has a hall of its own, and on entering we find a display of surgical and dental instruments, a model operating room, bandages, orthopædic instruments, &c. The operating tables are light, of enamelled metal, but there is no provision made for heating them, nor do they seem to present any particularly new feature. Asepsis appeared to be well observed throughout. There is also a model pharmacy in the German style. Messrs. Max Werner of Düsseldorf exhibit here various food buffets suitable for restaurants, clubs, &c., constructed on aseptic principles. The shelves are of plate-glass and the sides of enamelled tiles. Then there are partitions for holding ice and a system of ventilation by which the air must pass over the ice before it reaches the food. Undoubtedly there is in this a useful idea, for there is much room for improvement in the keeping of food both before and after it has been cooked. All around on the walls there are fine sectional drawings of the Düsseldorf Rhine embankment and the celebrated Koenigs Allee, showing the sewers, the water, and other underground services, together with the gullies for preventing the sand from reaching the sewers. But I failed to see how the sewers were ventilated. Then there are elaborate plans of asylums, hospitals, sanatoriums, schools, reformatories, slaughter-houses, and so forth. A photograph of the interior of the lying-in ward of the Aix-la-Chapelle Maternity shows that the infant incubators are used in that institution. The photographs of the children's colonies at Wiesbaden are interesting as indicating what can be done for weakly children coming from overcrowded large towns. Some of the great factories exhibit health statistics of their workmen and there are here more toy models of workmen's dwellings. The great work done by private charity in providing employment and shelter for tramps is likewise explained by publications and photographs. Then there are large plans of the Eberfeld and other hospitals and a very fine model of the Dortmund irrigation farm for the disposal of sewage, together with maps and illustrations of the Düsseldorf drainage scheme, the sewer outlet in the Rhine, and the various levels of the river water. Each of these subjects, and many more that I have not mentioned, would supply material for a lengthy study. For instance, there is a middle-class society which has for its purpose the provision of suitable country homes for the treatment of 130 of its members who are suffering from phthisis. Such a movement cannot be described in a few lines, nor would it be safe to venture upon an opinion without a very close investigation of the whole question. In this section therefore, many interesting problems are raised. There is here much food for thought but all these subjects must be studied separately and in detail. Fortunately, a very excellent description of the entire section has been published for the modest sum of 2*s.* It has been prepared by 20 different authors or compilers who, between them, have addressed 2500 questions to the exhibitors concerned. Anyone, therefore, who has time to study this book and then to visit the section in detail would find much here to repay the trouble and would also obtain a general idea of the progress made of late in Germany. As a recreation after such serious investigations there are a few side shows. A miniature Switzerland with an Alpine village and a splendid panorama is well worth a visit, while opposite there is a Cairo street with dervishes, Bedouins, odalisks and other phases of oriental life. Bands, restaurants, and beer-gardens attract the weary visitor on all sides and sweeping past in front of the entire exhibition is the majestic Rhine thronged with pleasure boats suggesting pleasant excursions in various directions.

Düsseldorf, June, 1902.

THE SWISS MEDICAL CONGRESS.

(FROM OUR OWN CORRESPONDENT.)

THE central committee of Swiss medical men held their annual spring meeting at Berne on May 30th and 31st. It was attended by about 200 medical men from all parts of Switzerland.

Professor KOCHER demonstrated a number of cases at his Clinique. A case of fracture of the left parietal bone in a child had called for surgical interference as craniometry and the clinical symptoms localised the lesion and pointed to destruction of brain tissue; there were hemiplegia and aphasia. The operation, which took place three weeks after the accident, was completely justified, a portion of bone being found to be detached and fixed transversely in the brain tissue, while meningocele had commenced. Such cases often gave rise in later years to epilepsy. The most experienced were sometimes at fault in their diagnosis of sarcoma of the antrum of Highmore, where rapid growth seemed to point to inflammation and suppuration only. In one case, that of a girl, aged 10 years, Professor Kocher diagnosed sarcoma. Tapping the antrum showed that fluid was present, but Professor Kocher persisted, opened the antrum, and examined the mucous membrane, which appeared to be normal. He then excised a small portion, microscopic examination of which proved that sarcomatous tissue had invaded the normal structure. A radical operation was thus indicated and performed. To improve the appearance of the face Professor Kocher made injections of paraffin into the subcutaneous tissue, where it remained *in situ* for months. For extensive operations about the mouth and the fauces he declined to perform preliminary tracheotomy, as he did not wish to accumulate dangers by adding a new operation.

Where the danger of pneumonia from inhaling septic substances was great he operated with the patient lying on one side and kept the patient in bed at night in the same position. The day after the operation the patient had to get up as expectoration was freer and the chances of recovery were improved. This method gave good results. He showed a case of tuberculous ulceration of the bowels operated on four and a half years ago. The ascending colon was so adherent owing to masses of secondary glandular tumours that an entero anastomosis had to take the place of a radical operation. The patient recovered and was fairly well for years but lately had come again for operation. Laparotomy revealed that the primary lesions had all healed, including the swollen glands, but now ulcers had formed higher up, leading to 11 strictures. He again performed entero-anastomosis, uniting the jejunum with the transverse colon, hoping thus to alleviate the sufferings of the patient. Convalescence was retarded by acute pneumonia occurring. Referring to cases of obstinate neuralgia of the trigeminal nerve he warmly recommended excision of the Gasserian ganglion as giving the best results and demonstrated a case in an old man, aged 70 years, who suffered pain so excruciating that he meditated suicide. The operation was a very difficult one and care had to be taken not to cut the facial nerve. In cases of so-called "distortions" of the joints he urged the practitioners to consult the surgeon. Cases left to themselves, especially knee cases, became hopelessly chronic and the joints never recovered their proper functions. Very often all that was required was suture of a torn ligament, a condition of things existing in two cases shown. Professor Kocher concluded his demonstrations by speaking on the operative results of diffuse peritonitis. A hernia in a labourer descended while he was at work, which he put back, as he said, without much difficulty. A quarter of an hour afterwards the bowel came down again. He returned it again somewhat energetically, but pain ensued, so that the patient was transferred to the hospital. Reduction *en masse* was diagnosed. Laparotomy showed the existence of fresh diffuse purulent peritonitis. On further examination rupture of the bowel was discovered to be the cause of the inflammation. The man had doubtlessly ruptured his own gut whilst performing reduction of the hernia; he mentioned that he employed considerable force "as he was in a hurry." Though such cases very generally proved fatal the man recovered and could be dismissed as cured. Professor Kocher was of opinion that recovery was dependent on three facts: first, the possibility of removing the cause of the peritonitis, secondly, the proper disinfection of the peritoneum; and, thirdly, prevention of an accumulation of fluid in the peritoneal cavity, in which the microbes in question could develop. The peritoneum could absorb and render innocuous innumerable quantities of micro-organisms, but it could not perform these life-saving functions if fluid was allowed to accumulate. Professor Kocher prevented the accumulation of fluid by free drainage with three tubes. He always closed the peritoneum with a suture. At the close of his lecture Professor Kocher showed half a dozen cases of Basedow's disease cured by surgical interference. He proved them to be true instances of the disease both by clinical reports and by photographs. The successful results of these operations showed, he considered, that the disease was a hyperthyroosis. Professor Kocher performed preliminary ligature of the two superior thyroid arteries and then excised one half of the thyroid gland.

Professor SAHLI, professor of clinical medicine, spoke upon the Diagnosis and Treatment of Aneurysm of the Aorta. He disapproved very strongly of the treatment by gelatin injections. He then proceeded to discuss Diagnostic Methods in Diseases of the Digestive Tract. Their present methods gave doubtful results. They did not distinguish between fluid which they introduced and fluid which was secreted in the stomach. Professor Sahli had introduced a "butyrometric method" which his assistant, Dr. Seiler, had described at length. He introduced a test breakfast consisting of a carbohydrate in solution together with a known amount of fatty substance. After performing lavage the percentage of fat was again determined and he obtained the data he wanted to know. The acidity could thus also be determined more correctly. Professor Sahli had also investigated in a most detailed manner the question of the origin of motor insufficiency of the stomach. At present exclusive stress was laid on *mechanical* causes; these called for operative interference which was sometimes unnecessary. The new physiological school (von Mering, Moritz, &c.) had drawn their attention to the reciprocal influences of intestine and stomach. In health all went well even if each organ looked to its own interest. In case of disease discordant action ensued. The intestine could close the pylorus by reflex action as soon as the stomach evacuated improperly digested food containing noxious substances, such as a surplus of hydrochloric acid. In such cases of obstruction there need be no hypertrophy of the pylorus or any stenosis whatever. In cases of retarded intestinal digestion with retention of a surplus of food, together with insufficient peristalsis, the intestine shut the pylorus by reflex action in self-defence. How could the peristaltic force of the stomach be determined? Certainly not by means of the usual test breakfast. Only *pure water*, say one pint, must be introduced; any addition might provoke the reflex action (von Mering) of the pylorus and lead the observer into false conclusions. Lavage with due precaution would, after one or two hours, demonstrate whether this fluid had passed on into the intestine. To test the permeability of the pylorus Professor Sahli first determined the shape of the stomach and the position of the pylorus by inflation, then introduced a round piece of cork into the stomach, and kept it floating on water so that it could easily pass the pylorus. The patient must occupy a special recumbent or inclined position according to the dimensions and position of the stomach. If the piece of cork was afterwards found in the fæces the permeability of the pylorus was proven. The piece of cork had a diameter of one centimetre.

Professor STOOSS demonstrated the newly-erected Children's Hospital and spoke on Barlow's Disease, which seemed to be fairly rare in Switzerland. He also showed an interesting and very rare form of Miliary Tuberculosis of the Skin in a tuberculous infant.

On the afternoon of May 30th Professor KOCHER spoke on So-called Primary Tuberculosis of the Intestine. There were about 80 cases on record. Professor Kocher reported about 29 cases, in 21 of which he operated. The fact that primary tuberculosis was so rare spoke in favour of the thesis that Koch supported at the British Congress on Tuberculosis, that the disease was not transmittable from animals and that bovine and human tuberculosis were two different diseases. Secondary tuberculosis was very general; 500 out of Fenwick's 863 cases of consumption had some tuberculous lesions in the intestines. Professor Kocher wished to call his cases localised tuberculosis of the intestines, yet the previous history of the patients was generally doubtful as to freedom from tuberculosis, for they came from a tuberculous stock or had suffered from lengthy bronchitis or even pleurisy, or in infancy from glandular swellings; thus there was a possibility or probability of there being some primary latent tuberculous focus somewhere. In cases of constipation infection of a slight lesion with tubercle bacilli was possible; generally the ulcers were localised in the cæcum. Ulcerations were followed by stenosis, the multiplicity of the ulcerations excluding the diagnosis of carcinomatous ulceration. For the diagnosis the diazo-reaction was of importance; the symptoms might be very slight; only localised recurrent pain might assist the physician who should do all he could to get the patient into the surgeon's care in the first ulcerative stage, where excision could still be performed. Generally the surgeon only saw the patient in the second stenotic stage suffering from all the symptoms of the chronic form of ileus with intermittent symptoms. Large glandular tumours lead to false diagnosis, such as floating kidney, for the tumour might have a smooth surface and be very moveable; the age of the patients (from 20 to 30 years), also their relatively good physique, generally excluded cancer. If an ulcer perforated fatal peritonitis ensued, or a chronic form of peritonitis that was often diagnosed as "recurrent appendicitis." Excision gave the best results, while entero-anastomosis was a fairly satisfactory palliative operation. It was desirable to feed patients with ulceration of the bowels probably due to tuberculosis exclusively on *sterilised* milk diet out of sterilised cups or glasses. This might induce or promote a cure.

Professor GIRARD of Berne and Professor MULLER of Basle spoke respectively on the legal and ethical side of the question of professional secrecy with regard to the desirability of a paragraph being inserted in the new Federal Law. This was not considered desirable.

FOREIGN UNIVERSITY INTELLIGENCE.—*Vienna*: Dr. Ritter Friedländer von Malheim and Dr. Oscar Föderl have been recognised as *privat-docenten* in surgery.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Decline of the Plague Epidemic.—Increase of Famine: Monsoon Prospects.—Diphtheria in Calcutta.

THE mortality from plague throughout India during the past week has shown a great improvement. As the epidemic has been raging during the hot weather of the past month or more this decline must be attributed to the natural course of the disease rather than to seasonal changes. There has been a diminution of over 4000 in the number of deaths, the returns giving 7008 deaths, as against 11,612 during the previous seven days. In the corresponding week last year there were only 1918 deaths from plague. The decrease has been general throughout India, but the chief drop has been in the Punjab. The virulence of the disease seems to lessen with the subsidence of the epidemic. In the Lahore district 547 deaths were recorded with 1164 seizures, but from experience in some of the chief cities I should say that it is very doubtful about all these living cases coming under observation. In Calcutta there is a decline from 280 to 209, in Bombay city from 391 to 300, and in Karachi from 122 to 65. In Bengal the deaths have fallen from 337 to 136, in the Bombay districts from 583 to 429, in the United Provinces from 417 to 266, in the Punjab from 9192 to 5453, and in Kashmir from 212 to 27.

While the plague is diminishing the famine is increasing. More than 8000 were added to the list this week, which now shows 431,000 people receiving relief. Of these, 346,000 are on relief works and 84,000 receive gratuitous relief. It is, perhaps, satisfactory to record that there is a prospect of an early monsoon. Rains are falling daily at Colombo. The western portion of the monsoon current is said to be promising. This is all-important to the districts affected with famine.

There is at present no indication that the dengue fever which has attacked Rangoon has as yet spread westwards. No cases have been reported in Calcutta. Diphtheria has, however, of late claimed several victims in the metropolis. This is a matter of some moment because hitherto the disease has been extremely rare; in fact, its existence has by some observers been denied. There is little doubt about it now and if faulty drainage and bad smells do in any way favour its dissemination there is plenty of opportunity for it to spread. There is nothing like an epidemic, but several cases have been reported.

May 24th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Sanatoriums for Consumptives.

THE Birmingham board of guardians has carefully considered the question of the open-air treatment of consumption and has resolved to build a hospital near the present infirmary at a cost of £332 for the reception of phthisical patients. Some doubt has been expressed as to the suitability of the site for the purpose, which is not one to make a favourable impression even upon the more ardent supporters of the movement. But the scheme is one of a desirable kind and is justified by the knowledge gained of the effects of the open-air treatment in other places. A largely attended meeting was held in the city on June 9th in support of this project. The meeting was presided over by the chairman of the health committee, Alderman Cook. In his opening remarks he reminded the meeting that when certain of the guardians waited some little time back upon the health committee of the corporation asking it to establish a sanatorium for the treatment of consumptives the request was considered "rather a large order." While supporting the scheme in principle he thought at that time that the committee had sufficient responsibility laid on it in providing hospital accommodation for infectious diseases and that it should not undertake additional duties in this direction. He considered prevention to be better than cure and that by improving the dwelling-houses of the poor in the city and by appointing lady visitors much had been done to prevent phthisis. It was pointed out from the returns that out of a total number of 10,402 deaths in Birmingham last year 903 were from consumption, and of these 243 occurred in the various workhouses of the district. The meeting appeared to support the view that open-air sanatoriums should not be promoted by the municipality but that private enterprise should be seconded by contributions from the rates for the purpose of maintenance. A similar proposition was recently made to the Worcestershire County Council, an offer of a house and grounds being made by a generous donor. It was resolved not to accept the offer as being outside the scope of the work entrusted to the council, but it was decided that there could be no objection to the vote of £300 a year from the council towards the support of the scheme if other adequate management could be found.

Medical Benevolent Society.

The annual meeting of this society was held on May 30th, a satisfactory report being issued by the directors. It was shown that the invested funds amounted to £15,568. 18 annuitants were on the books, the annual grants being from £20 to £40. The total number of members was 405. Attention was drawn, as usual, to the large number of practitioners in the neighbourhood who had not availed themselves of the advantages of membership of the society. The area of the society's operations comprises a 50 miles radius of Birmingham and a vast amount of good might be done by an increased number of members. A dinner, which was subsequently held, was well attended by the members and their friends.

An Untimely Death.

The town is the poorer and the University the sadder by the early death from sarcoma of one of their most brilliant sons, Mr. William Henry Austin. After a most successful educational career at King Edward's School and Mason College Mr. Austin went to Cambridge where he graduated as Senior Wrangler in 1897. Subsequently he became mathematical lecturer at the University of Birmingham, being assistant to the vice-principal, Dr. Heath. Ardent, enthusiastic, and of exceptional abilities he soon became a power in the teaching staff of the University.

June 10th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Liverpool Infectious Hospitals.

AN inquiry was held at the Municipal Buildings by Dr. S. W. Wheaton, Local Government Board inspector, in reference to the application of the Liverpool City Council to borrow £16,500 for the purposes of the city hospital at Fazakerley and the small-pox hospital at Fazakerley, respectively. Mr. Cripps, the solicitor to the city council, stated that a letter had been received from the Local Government Board complaining that in regard to the expenditure of £20,000 on infectious hospitals at Fazakerley sanctioned last year the plans had been departed from, wooden buildings having been substituted for more substantial structures. The Board regarded this as very unsatisfactory and would instruct the inspector to inquire fully into the circumstances of the deviation. It appears that the two wooden pavilions were erected on the advice of the medical officer of health who represented that the accommodation for infectious cases was inadequate whilst an epidemic of scarlet fever was threatening the city. The chairman of the hospitals committee of the city council and the medical officer of health had an interview with the officials of the Local Government Board and came away under the impression that the modified scheme was approved. Later a small-pox scare occurred and accommodation being quickly required for small-pox patients nearly the whole of the money which was the subject of the present inquiry had been spent. Altogether the corporation intended to spend £42,000 and would apply for sanction for a further loan. Only £4816 had been spent on temporary buildings. The chairman of the hospitals committee, Dr. E. W. Hope (the medical officer of health), and the city surveyor spoke of the urgency of the matter and of the great advantages which had accrued from the temporary buildings in stamping out the outbreak of scarlet fever and small-pox. The chairman of the hospitals committee said that a marked change of public feeling had taken place in regard to these hospitals. Formerly it was difficult to get patients to go to the hospitals but now they clamoured for admission. Dr. Hope said that the committee had 700 beds available for ordinary infectious cases, 180 beds for small-pox, and 40 beds for sea-borne cases. Of the total 300 beds were on a site which did not belong to the corporation and it was proposed to replace these on land acquired by that body. To emphasise the urgency for further hospital accommodation it was pointed out by Mr. J. Utting, M.R.C.S. Eng., L.R.C.P. Edin., a member of the city council, that not long since 200 persons applying for admission could not be accommodated through lack of beds.

The Oliver Lodge Fellowship.

Mr. Charles G. Barkla has been elected to the Oliver Lodge Fellowship recently founded at University College, Liverpool, to promote research in physics. Mr. Barkla is a former student of the college and after graduating at the Victoria University was elected to one of the research scholarships by the Royal Commissioners for the Exhibition of 1851. As Oliver Lodge Fellow he will work in association with Professor Wilberforce in the physics laboratory at University College and will assist that gentleman in physical research. The annual value of the Fellowship is £100 and the holder is eligible for re-election. The Fellowship was founded in honour of Principal Oliver Lodge of Birmingham University, formerly the professor of physics at University College, Liverpool.

Bolton Infirmary Inquiry.

Judge Bradbury's report on the allegations of mismanagement at the Bolton Infirmary was issued on June 6th. His honour holds the charges of negligence of the staff in the treatment of patients entirely to be unfounded; neither was there any ground for the charge of negligence and inability of the house committee to manage the institution. It was admitted, however, that certain members of the honorary medical or surgical staff had received payment for professional attendance on patients at the infirmary. This was held to be a breach of the rules of the institution and was to be regretted. The judge also held that the refusal of the infirmary committee to admit the medical advisers of employers to examine patients could not be justified. With the exception of the two points indicated, which in no way affected the efficiency of the institution, the work had been carried on in a highly satisfactory manner and deserved the entire confidence and support of the public. As funds were required the judge enclosed a donation of £10, thus showing in a practical manner his appreciation of the good work at the hospital.

Proposed Coöperative Convalescent Home at Liverpool.

The Coöperative Union, Limited, North-Western Section, held a sectional conference at Blackpool last week with the view of deciding as to the establishment of convalescent homes on the lines of the Scottish Coöperative Convalescent Home, West Kilbride, Ayrshire, as a health-giving resort for indigent coöperators. Two convalescent homes are contemplated—one on the coast and one inland, probably in Yorkshire. Meantime the idea is to erect one at Norbreck, about two miles from Blackpool, at a cost of £25,000. The committee proposes to raise the money by shares, so that each coöperative society becoming a member of the Coöperative Homes Association may take up a £1 share for every 40 of its members, and for every £1 subscribed a society may be entitled to a recommendation.

June 10th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Resignation of the Medical Officer of Health of Gateshead.

Dr. Reginald Green, the medical officer of health of Gateshead, who has resigned his post, has been unanimously elected by the King's Norton Urban District Council to be medical officer and medical superintendent of the isolation hospital. Ten years ago Dr. Green graduated in medicine and surgery at Durham University; he was appointed junior medical officer of the Gateshead Dispensary and while working there he took his M.D degree. A little later he took his B.Hy. degree, having been trained in the Newcastle Sanitary Department. A vacancy occurring Dr. Green was appointed medical officer of health of Gateshead and about a year ago took the D.Hy. of Durham University. Dr. Green will be much missed in Gateshead, where he had become generally popular and not least amongst his professional brethren.

Consumption Sanatorium for Northumberland.

It is now some considerable time since the first sanatorium for consumption was built in the United Kingdom and ever since sanatoriums have been springing up in many of the different counties of England with one notable exception—Northumberland. The Northern Counties Hospital for Consumption and Diseases of the Chest made an attempt to collect subscriptions for this purpose many months ago and was successful in collecting about £1000. This is practically where the matter rests except for a public meeting which was held at the Royal Infirmary some weeks ago, at which meeting a free site was promised for the proposed sanatorium. This site, however, is a long distance from Newcastle and would be consequently difficult of access. One reason, perhaps, why more interest is not taken in this matter is the fact that the authorities of the Royal Infirmary are pretty fully occupied with the building arrangements of the New Royal Victoria Infirmary, but seeing that it will be almost four years before this building is finished and probably two more before it is in full working order I think that this matter is sufficiently pressing to require more attention than it has hitherto received. The building of the new infirmary is making slow but perhaps satisfactory progress. A large number of the foundations have been laid and this has entailed a very large amount of excavating work which, however, does not appear a great deal to the casual passer-by.

June 10th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Rhondda Health Report.

DR. J. D JENKINS, the medical officer of health of the Rhondda District Council, has just issued his first annual report, from which it appears that the estimate of the population made by the Registrar-General was not realised at the census of 1901, the official estimate being more than 20,000 in excess of the 114,000 persons actually enumerated The death-rate during 1901 was 21·6 per 1000, and the infantile mortality rate of 222 per 1000 births was only exceeded in one of the 33 great towns of England and Wales—viz., Burnley, where the rate was 223 per 1000 births. The birth-rate was 40·1 per 1000. The prosperity of the district is indicated by the fact that of the 19,578 houses only 134, or about one in every 200, were uninhabited at the time of the census enumeration. The division of one house into two tenements is strikingly shown in the statement that among 2399 houses in which infectious disease occurred in 1981 as many as 1270, or more than half, were occupied by more than one family. The average number of persons in these infected houses was 6·7, while for the whole district the average number per house was only 5·9 The water-supply of the Rhondda appears to be anything but satisfactory. One portion of the two valleys is supplied from works owned by the district council which obtained powers several years since to supplement its supply either by sinking below the coal measures or by enlarging the present catchment area. No progress has been made with either of these schemes and during summer drought supplementary supplies are obtained from undesirable sources, such as disused levels, while street watering and sewer-flushing have to be discontinued when they are most needed. To this last, indeed, Dr. Jenkins attributes in some measure the large amount of autumnal diarrhœa—as many as 327 deaths, equal to a death-rate of 2·85 per 1000—occurring during 1901. The portion of the district served by the Pontypridd Waterworks Company had an intermittent supply for more than two months during the summer of 1901 and the water was frequently discoloured. This discoloured water has in former years been the indirect cause of serious outbreaks of typhoid fever and it is a little difficult to understand why the district council does not insist upon efficient filtration.

Compulsory Closure of Sunday Schools.

In consequence of an extensive outbreak of measles in the district the medical officer of health of Blaenavon in Monmouthshire (Mr. A. B. Avarne) has advised the sanitary authority to require the closing of the public elementary schools for three weeks and has requested the religious bodies to close their Sunday schools for a like period. This action on the part of the medical officer of health was very much resented by a clerical member of the school board, who objected to close the Sunday school with which he was particularly connected and brought out the oft-exploded argument that disease was much more readily spread by children visiting one another's houses during the time the schools were closed than if they were congregated in school-rooms holding 40 or 50 scholars. The question of closing Sunday schools in Wales is always a difficult one to deal with and prompt day-school closure is frequently rendered of no avail on account of the assembling of children in schools on Sundays.

Treatment of Epileptics.

At the Poor-law Conference for South Wales and Monmouthshire which was held at Abergavenny on June 5th Dr. J. Milson Rhodes of Manchester opened a discussion upon the treatment of epileptics. Dr. Rhodes in the autumn of last year visited several colonies and special hospitals for epileptics in the States of New York, Ohio, Pennsylvania, Maryland, and Massachusetts, and has recently presented a report upon his visit to the committee of the proposed colony for epileptics to be established at Warford, near Manchester, so that he was able to put before the conference many details and suggestions of importance. Mr. F. T. Bircham (Local Government Board Inspector for Wales) suggested that an epileptic colony and an idiot school should be established for Wales where non-pauper as well as pauper cases might be treated, and it was eventually decided to approach the county councils of South Wales and Monmouthshire on the subject. The question has already been discussed within the past three years in the Glamorganshire County Council and endeavours to obtain information from private practitioners in the county as to the approximate number of non-pauper patients who would be likely to take advantage of such an institution if one were established were made.

Outbreak of Glanders.

An outbreak of glanders has occurred in the stables of the Pontypridd Tramways Company of such a serious character that the service on the short four-mile length of tram lines between Pontypridd and the Rhondda valleys has been discontinued. The Health Committee of the Glamorganshire County Council has recommended that all the horses belonging to the company should be slaughtered and that the council should pay to the company £2 for each horse found after post-mortem examination to be affected and full value for each animal not affected. This action on the part of the council is to be commended, for the disease might readily be carried to the horses stabled and working underground, of which there are many hundreds connected with each colliery.

Vaccination Questions.

At the meeting of the Exeter Board of Guardians held on June 3rd it was reported that there had been an increase of 1700 vaccinations and revaccinations as compared with the corresponding quarter of 1901. A discussion took place owing to the fact that persons who could well afford to pay the fees had been revaccinated at their homes at the expense of the ratepayers. One guardian proposed that these persons should be asked to refund 2*s.* 6*d.* each, being the difference between the cost of revaccination at their own homes and at the public vaccinator's residence. This was seconded. Another guardian wished to have the names published in the half-yearly reports as the recipients of parochial relief. Eventually, after it had been explained that people had a right to be vaccinated where they liked, the matter dropped.—At the meeting of the St. Germans (Cornwall) Board of Guardians held on June 5th it was stated that the vaccination fees for 1901 amounted to £29, whereas this year the amount was already £160. The finance committee recommended that revaccinated persons who were thought to be able to pay for the operation should be asked to do so. The chairman said that his name would be on the list and it was stated that the names of colonels, bankers, magistrates, and ex-judges would also be found. One gentleman had all his servants revaccinated at one time, costing the ratepayers £8. It was, however, explained to the guardians that everybody was entitled to be vaccinated free of cost.

June 9th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Association for the Prevention of Tuberculosis.

THE annual meeting of the Dublin Branch of the National Association for the Prevention of Consumption and Other Forms of Tuberculosis was held on June 9th in the Hall of the Royal College of Physicians of Ireland, the President, Sir Christopher J. Nixon, being in the chair. The honorary secretary read the annual report which dealt with the failure of the public health committee of the corporation to bring about voluntary notification of pulmonary tuberculosis and with other matters. The report alluded to the fact that no provision exists in Dublin for the examination of the sputum of consumptive patients who are unable to pay a fee and to the necessity for a city bacteriological laboratory for the purpose of dealing with cases of tuberculosis as well as with patients suffering from diphtheria, enteric fever, and other infectious diseases. The adoption of the report was moved by the President of the Royal College of Surgeons in Ireland, Dr. Lambert H. Ormsby, who suggested that the Board of Agriculture and Technical Instruction for Ireland should include a bacteriological laboratory in the projected buildings to be erected in Upper Merrion-street. The Right Hon. Horace Plunkett, who was present, alluded to the matter later and said: "On the question of the establishment of a bacteriological laboratory which had been referred to by the President of the College of Surgeons, who had thrown out the suggestion that the department might include it in their multifarious institutions—they could not do it out of their own funds; but if the Treasury would defray the cost, and if the Colleges of Physicians and Surgeons would assist them to run it they would be very glad to add it to their responsibilities." The chairman in closing the proceedings bore testimony to the invaluable assistance given to the association by the Lord Lieutenant from its commencement. Referring to the establishment of a sanatorium for consumption he remarked that it was discreditable that the city of Dublin, in which the hospitals generally were out of all proportion greater than the wants of the people, should have nothing in the shape of such a sanatorium.

Royal College of Surgeons in Ireland.

The new Court of Examiners in Surgery at the Royal College of Surgeons in Ireland to hold office for the coming year has recently been elected as follows:—Dr. F. Conway Dwyer, Mr. Thomas E. Gordon, Mr. Joynt, and Dr. Edward H. Taylor.

The Outbreak of Small-pox in Belfast.

Up to the present time the number of cases of small-pox admitted into the fever hospital in the Belfast Union is 22. The type of the disease is so far, on the whole, mild, with a few severe cases, one of which, that of a woman, aged 70 years, proved fatal. No new cases have been admitted since June 5th. As stated in THE LANCET of last week, the public health committee has decided to erect temporary buildings for small-pox patients at Purdysburn, a course of action which has aroused considerable opposition. In the first place, at a meeting of the asylum committee on June 9th the resident medical superintendent of the Belfast District Lunatic Asylum, Dr. William Graham, pointed out that it was the duty of the committee to take every precaution for the protection against infection of a body of helpless and irresponsible persons, many of whom were quite incapable of exercising that forethought and prudence which sane persons adopted in protecting themselves against the risk of contagion. He pointed out that some of the blocks of the proposed permanent infectious diseases hospital were only separated from the asylum grounds by the county road, and that if the land was to be continued to be used for the patients' employment and recreation it would be absolutely necessary to isolate the infectious hospital ground by a high wall. Further, the present supply of drinking-water for the asylum was derived from springs rising from the infectious hospital site and once the buildings would be brought into occupation another supply would have to be obtained. Sir George P. O'Farrell, the Inspector of

Lunatic Asylums in Ireland, who was present, considered that either the hospital or the asylum would have to be abandoned. A permanent small-pox hospital near an asylum would not be tolerated in England in any circumstances. Of course, he referred to the permanent and not the temporary difficulty. Small-pox was different from any other disease and the distance was very great at which infection could be conveyed. A public meeting has also been held at Purdysburn, at which the inhabitants of the district—including the clergy, the medical men, and the farmers—protested very strongly against the proposal made by the Belfast Corporation to establish a hospital for the reception of small-pox patients at Purdysburn and called upon the Local Government Board to refuse its sanction. It was pointed out that other more suitable sites could be procured at a proper distance from inhabited houses and one of the speakers suggested the use of a hospital ship down the Belfast Lough—a course followed in other places. Some of the people who will, it is alleged, be most injured by the erection of the small-pox huts at Purdysburn are the dairy-farmers. The truth of the matter is the Public Health Committee of Belfast should have taken action years ago in the matter of the provision of an infectious diseases hospital and the present epidemic of small-pox will in the end have done good if it once and for all settles the question of the provision of a proper infectious diseases hospital. In the locale of the erection of the huts for small-pox cases the public health committee claims to have had the support of Dr. O. J. Clibborn, Local Government Board medical inspector, who inspected the site.

The Belfast Hospital for Sick Children.

At a special meeting of the board of management of the Belfast Hospital for Sick Children held on June 5th it was decided that the present hospital should be extended by adding sufficient accommodation for 10 new beds on the condition that no part of the expense should fall upon the existing funds of the institution. A sum of £250 has been promised to pay for the building until the funds show such an increase as will justify the board in adding these new beds. The extension is to be used for cases requiring quiet or special attention and will, of course, add to the air space and room of the wards.

PARIS.

(From our own Correspondent.)

The Law as to Workmen's Compensation and Medical Aid.

I HAVE on a previous occasion[1] referred to this new law, the application of which is full of difficulties and which though well intentioned is so badly drawn that in one way or another it offends all parties who have to do with it, whether workmen, employers, insurance companies, or medical men. As, however, the courts practically always find the workmen to be in the right the new law is a simple exploitation of the employer by the workman. The latter is in his turn preyed upon by unscrupulous inquiry agents (*agents d'affaires*) who get up his case and share the sum paid over for compensation. Medical men are also much concerned with the law and its difficulties. I have already mentioned how in the case of an accident the injured person is almost invariably taken to a hospital whether he be able to pay for medical attendance or not. Hospital surgeons are therefore often obliged to treat for a very small fee those who are perfectly able to pay, or those for whom a wealthy employer could pay the usual fees. The insurance companies also suffer, for the employer generally comes down on them. The companies, as is only fair, argue that the injured man should be attended by some medical man appointed by themselves. The law, however, says that the injured man may choose his own medical attendant, also a fair proviso. But the law also says that a medical man so called in shall only be paid at the reduced rate laid down for gratuitous medical assistance. If, then, a drunken carter who had fallen out of his cart were to call in a professor of the faculty of medicine, such professor would be paid at about the rate of two francs per visit. Naturally the professor would refuse to attend, which he would be quite within his rights in doing, and so it comes to pass that the workman's choice is in reality limited to that class of practitioner which accepts such small fees. The new law is much less beneficial to the workmen than was the old. By the latter the employer was simply obliged to see that the workmen received treatment and it might be that he sent his own medical man. By the new law the workman chooses his own medical man and, as a rule, will not have the medical officer of the insurance company, for he thinks that this practitioner's sole desire will be to get him back to work as soon as possible. Accordingly, he generally selects an unscrupulous practitioner chosen by the *agent d'affaires* who naturally wishes to prolong the illness and to increase the number of visits because he wants to get as much compensation as possible out of the insurance company to divide with the workman. The insurance companies are quite alive to this risk and they now demand that a medical man appointed by themselves shall visit the patient at least once a month in order to see how he is getting on. This is only fair and is the system employed by all the Government departments, for when an employé of one of those department is ill the medical officer of his department makes a visit of inspection from time to time.

Recognition of the Typhoid Fever Bacillus.

M. Chantemesse last year gave an account of a new method for the rapid recognition of the typhoid fever bacillus in suspected water or in the stools of patients. The essentials of his procedure consisted in obtaining superficial colonies upon carbolised agar, in cultivating them in a medium containing lactose and litmus, and in identifying them by agglutination with serum. M. Chantemesse has now simplified and shortened his method by adding the lactose and the litmus to the carbolised agar and he described the modification to the Academy of Medicine on May 20th. The process has now become very simple and is well adapted for clinical use since it gives results in 12 hours and requires only the ordinary media used in all laboratories. When suspected water is to be examined a large quantity of it is filtered through porcelain and culture media are inoculated with the residue separated by the filter.

Various Methods of Infant Feeding.

At the meeting of the Therapeutical Society held on May 14th M. Créquy said that he considered that bottle-feeding of infants was greatly inferior to breast-feeding. He was not an advocate of sterilised milk, for many infants had a difficulty in digesting it and many mothers relied on sterilised milk to the neglect of breast-feeding. Sterilised milk, moreover, tended to discourage the use of asses' milk, a substance which was of great value in certain forms of diarrhœa in infants and of gastric irritability in adults. M. Créquy maintained that there were differences in the milk of cows according to the breed of the animal. The milk of Dutch cows, for instance, was less rich in fat than was the milk of Normandy or Brittany cows, and this was the reason why the former was often preferable to the latter.—M. Bardet remarked that asses' or goats' milk was very expensive and therefore of restricted application; sterilised milk, on the other hand, had much in its favour and was distributed in the *crèches* to thousands of infants every day.—M. Sevestre said that asses' milk did not keep well and that sterilised milk generally agreed with the stomach, especially if it was freshly prepared.—M. Boulonié said that he was in favour of sterilised milk, for many women could not suckle their infants and would have to entrust them to wet-nurses if sterilised milk were not available.

June 10th.

EGYPT.

(From our own Correspondent.)

The Lunatic Asylum.

IN spite of much that has been done during the last 18 years to improve the question of lunacy in Egypt there is yet more which requires redress. There is still only one asylum of 500 beds for a population of more than 10,000,000, and it is in consequence always inconveniently full. Harmless cases, or rather those which are apparently harmless, cannot now be admitted. An Egyptian lunatic must prove that he is dangerous and unmanageable before the Government will recognise that it has any responsibility towards him, and if during his stay in the asylum he settles down into a quiet and apparently inoffensive individual he has too often to be discharged in order to make way for urgent arrivals from the country districts. During the past year, for instance, 1056 lunatics were under treatment but 326 of them were discharged still insane. Consequently it is found that more than one-third of the cases admitted had previously been inmates, for the majority of these re-admitted cases should never have been discharged. The number of Europeans admitted during the year has diminished and this is probably due to the introduction of legal certificates which require a consul's guarantee for payment. When I last wrote about the asylum the criminal lunatics were all kept in the same wards as ordinary lunatics, but now the Prison Department has recognised its responsibility in the matter and 63 criminal male lunatics were sent last year to the hospital in connexion with the Tourah convict establishment near Cairo.

---

[1] THE LANCET, July 20th, 1901, p. 176.

In the large towns lunatics are probably not now ill-treated, but in far away villages where civilisation has hardly yet entered the insane are stoned, ridiculed, and incited to violence in the streets, while in their homes they are sometimes tied down or chained until ulcers form on their limbs (Dr. J. Warnock says that 29 patients admitted in 1901 bore the marks of ropes or chains) and their friends rub hot irons into their heads and backs, disfiguring them for life and causing weeks of needless torture. One's sympathy is entirely with the lunatic who has been known occasionally to turn on his persecutor and murder him. No less than 76 cases admitted last year bore scars of the actual cautery.

The structural improvements which have been many years in progress to convert the old palace buildings into a convenient hospital have now been completed at the very small cost of £21,000. Access to every part is now made more convenient, four new staircases have been built, and the administrative portions are separated from the patients' sections. Sanitation, ventilation, and lighting are completed and the asylum is one of the first hospitals in Cairo which has been provided with an electric light installation. The petroleum burnt every night to work the engine and dynamo is about as costly as the lamp oil previously used for lighting. The basement floors have been relaid with mosaic concrete and in the upper floors polished pitch-pine boards have replaced the old decayed and absorbent limestone. Among other economies the hospital sewage which used to be carted away at an annual cost of £105 is now dug into the desert land by the patients without any expense. It has often been pointed out that this is an ideal place for a sewage farm—free labour, free land, sewage undiluted by an excess of rain-water, and a market close at hand for the sale of vegetables and clover. The milk-supply now comes from buffaloes kept on the premises, for this is found to be more economical than buying watered milk from contractors.

Perhaps the greatest improvement of all is that the patients are now divided into sections of 35 each instead of being a confused herd as formerly. Each section is now to a great extent independent of every other section and individual attention to the patients has become possible. The ignorance of the attendants, who are all natives, is now the worst part of the asylum. 10 men were dismissed in the year for ill-treating patients and it is significant that 11 female and 10 male patients sustained fractures of bones in the asylum. Only one-tenth of the attendants know how to read and write and Dr. Warnock "finds it safer to confine an irritable excited patient in a single room than to trust him outside to the care of an incompetent or even unkind attendant who, instead of conciliating the patient, often provokes further excitement or accident by his injudicious conduct." The remedy for this and for some other defects is to appoint two English head attendants to instruct the men and women in their duties, but this will be impossible until the financial authorities grant the necessary salaries. Mechanical restraint is never used in the asylum now except to prevent the removal of surgical apparatus or dressings. Anyone who has closely followed the reforms of this asylum is amazed at what the present superintendent, who is the only resident European, has been able to do, but as it was obvious that help must be granted him Dr. Dudgeon, lately of the Cane Hill Asylum, has now been appointed as his assistant.

Monthly returns show that the greatest number of patients are admitted in the two hottest months of the year—June and July—and it is chiefly during the summer months that the excited patients are most troublesome. This is one of the reasons for thinking that a second asylum should be built near Alexandria rather than in Cairo, which is always hotter, and this will be the obvious place for providing in the future some accommodation for insane Europeans, so that they could eventually be shipped to Europe. But the various European communities must arrange this, it does not fall within the scope of the Egyptian Government at present.

Out of 561 patients admitted during 1901, 181 were classified as suffering from mania, 91 from different forms of hasheesh insanity (*Cannabis indica*), mostly being mania, 33 had pellagrous melancholia or dementia, 25 had general paralysis, and 12 were not insane at all. The general paralytics, who included nine women, were almost all syphilitic and came chiefly from the large towns; 21 of them were Egyptians, the remaining four being Persian, Greek, French, and English. Among the known causes of insanity in Egypt hasheesh comes first, then pellagra, grief, syphilis, epilepsy, and alcohol in the order named. Therefore the two crying ills for the Government to fight are hasheesh and pellagra. The total number of deaths last year was 75, to which general paralysis contributed 18, exhaustion from mania and melancholia 15, and pellagra 10 cases. In England asylum accommodation is maintained for exactly 50 times as many lunatics as are provided for in Egypt per head of population.

Cairo, June 2nd.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Nurses in America.

THERE has been in New York—principally perhaps on account of the scandals in connexion with the nursing at Bellevue—an outcry against male nurses and a demand that female nurses shall be substituted for them. A recent article in the *Nineteenth Century* on the subject of Nursing in England is likely to modify somewhat the views of the enthusiastic supporters of female nurses here, although possibly the article in question is exaggerated and conveys on the whole a wrong impression regarding nurses in England, nevertheless it doubtless contains a substratum of truth. Nurses to be satisfactory must be thoroughly trained and it is the belief in America that hospital training alone is not sufficient and that a training school course is needful to produce a really efficient nurse. The personal factor, too, must always be taken into account, for like the poet the nurse is born and not made. Given other things equal, the female nurse for ordinary hospital work is superior to the male, and this opinion is beginning to take root in America.

The Good Side of the Meat Trust.

Most ills are said to be blessings in disguise; this is an exaggeration but there is probably no evil which has not some redeeming feature. In the United States at the present time the people are in the throes of a struggle with the meat trust, and meat has reached so high a price that the poor can scarcely afford to buy any, while the well-to-do are compelled to restrict its consumption. The *Medical Age* of May 10th, referring to the matter, says: "This probably will not be an unmixed evil. Meat three times a day, which it has been one of the glories of America to boast that she has provided for her poorest citizens, is certainly unnecessary. The pyramids were built on rice and corn, and much of the hard work of the world to-day is done by labourers whose daily quota of flesh food is much less than that which is normally consumed by the American." There is truth in this statement. The ordinary American eats practically an unlimited amount of flesh food, and perhaps to this fact are due the dyspeptic and uræmic tendencies of so large a number of the inhabitants of the United States. Meat once a day should be sufficient for a person not engaged in hard manual labour, and even then a surplus of flesh food does no good. The hardy Scotch peasant does his work on milk and oatmeal.

Mosquitoes and Dengue.

Much interest has been aroused by the publication in the *Medical Record* of an article by Dr. Harris Graham, professor of pathology in the American College, Beyrout, Syria, relating the result of his investigations concerning the parasite of dengue and the probable position of the mosquito as the intermediary host in the transmission of the disease to man. This was referred to in THE LANCET of March 22nd, p. 855. Most of the American medical journals have taken notice of

On Nov. 24th the discharge pipe from the last cesspool into the river "was discovered and further infection from that source prevented. Not more than 28 cases were infected after this date and of the 28 cases 18 were infected within the first week and seven within the second week after it. Thus it appears that within two weeks of the shutting off of fresh infection the typhoid bacilli already in the river had practically disappeared owing to surrounding conditions not being so favourable as in the cesspools and to the effect of the downward flow of the current. It seems reasonable to believe, however, that the infection of the river and its attendant results might have continued indefinitely, owing to the conditions favourable to bacterial life existing in the cesspools, had not those sources of infection been discovered and cut off."

In the twenty-fifth volume of the reports and papers of the American Public Health Association for 1899 Dr. Leal reported on an outbreak at Paterson which he showed was caused by the public water-supply derived from the river Passaic "which at least 98 per cent. of those infected were known to use for at least a portion of the 24 hours." In the course of his report he says "The suspicion thus cast upon the public water-supply as being the only factor common to the case was confirmed by the following facts: First. The only section of the city in which the disease did not appear is the only section not having the public water-supply. Second. The city of Passaic, supplied from the same source, was found to be suffering from an outbreak of typhoid fever at the same time. Third. The course of the epidemic was marked by sudden rises and falls. Fourth. Those rises and falls were preceded by heavy rains and, consequently, rising waters." He found that the outbreak was caused by the excreta from a case of typhoid fever which developed during the early part of August, 1898. "The drainage from the premises of said patient was through a pipe into a small tributary of the Passaic river about 8000 feet above the intake. The local board of health, learning of the case on August 23rd, at once cut off drainage from said tributary, so that infection directly from said case ceased on that date." The water from the tributary had to run through a swamp before joining the river and refuse from a glue and gelatin factory also contaminated the waters of the tributary.

The theory evolved by Dr. Leal from these facts is as follows. "That the said tributary was infected from said case of typhoid while high from the heavy rain of August 10th; that the infected water of tributary spread over said swamp and, falling, left numerous pools, puddles, &c., cut off from the natural channel. That *in these pools*, puddles, &c., existed the conditions favourable to the vitality and multiplication of the specific bacilli, these conditions being the low dilution, the unusual amount of organic matter on account of the glue and gelatin factory, the close and rank vegetation, &c. That a certain number of these bacilli were washed down the river by the rising water following each rain, with a certain amount of damage as a result—the greater the rainfall the greater the amount of damage done. That the infection of new cases ceased after the first week in February is explained by the fact that the general thaw following the heavy rain of Jan. 24th changed said swamp into a raging torrent, thoroughly washing it out and keeping its entire area under three to 10 feet of water for two or three weeks."

An interesting report by Dr. H. C. H. Herold, the president of the Board of Health, on an outbreak at Newark, New Jersey, is contained in the same volume. It appears that Newark was formerly supplied by the Passaic river, the water of which was contaminated, but that in April, 1892, that supply was abandoned and a supply known as the Pequannock water system was adopted. After this there was a steady decrease in the number of cases of typhoid fever until 1898 when there was a marked increase, especially in August and September. This was found to be due to shortages in the daily Pequannock supply having been met by *turning in contaminated* water from the Passaic river.

My friend Dr. Pistor of Berlin has kindly forwarded me a copy of a report by Dr. Räuber of Remscheid (Rhine Province) on a serious outbreak in that town in 1900. There had been a few cases yearly since 1890 and a small outbreak in 1899, but in 1900 the number of the cases rapidly increased until there were no less than 118 cases between July 9th and 21st. The cause was found to be from the water of one of the streams contributing to the water-supply having become polluted (*Zeitschrift für Medizinalbeamte*, Heft 19, 1901), and also one by Dr. Mewius of Cosel (Silesia) on an outbreak at Loukan and two other villages on the course of the same ditch which supplied them with water and which was contaminated by the excreta of two typhoid fever patients in a cottage higher up (*Zeitschrift für Medizinalbeamte*, Heft 17, 1900).

Dr. Maclean Wilson reported in 1893 on a sudden outbreak of typhoid fever at Chester-le-Street (Durham) which was followed after a short interval by another equally sudden. The sufferers in both cases were almost entirely persons using one public water-supply which had before the commencement of both outbreaks been contaminated by enteric fever discharges from some cases in a group of cottages about three miles above the intake of the water company. The sewage from these cottages ran by means of a covered drain into a small stream, a tributary of the Stanley burn which supplies the filter-beds of the company, but these filter-beds were quite inefficient for the purpose of preventing any germs of enteric fever contained in that water from gaining access to the street mains of the company.

Whereas the seasonal prevalence of typhoid fever is normally in the autumn months this disease is more prevalent and fatal in London during the winter months. Since 1890 I have pointed this out for St. George's, Hanover-square, for which I was formerly medical officer of health, and the following table from my report for 1900 shows that during every year except 1897, the monthly average for November and December was higher than that for August, September, and October.

Cases of Typhoid Fever.

Year.	August, September, and October.		November and December.	
	Number of cases.	Average per month.	Number of cases.	Average per month.
1891	6	2·0	12	6·0
1892	15	5·0	15	7·5
1893	16	5·3	18	9·0
1894	14	4·6	29	14·5
1895	11	3·7	10	5·0
1896	15	5·0	15	7·5
1897	16	5·3	6	3·0
1898	7	2·3	18	9·0
1899	14	4·7	11	5·5
1900	13	4·3	10	5·0

This rise in the number of cases of typhoid fever reported in the months of November and December "is coincident with the increase of organic matter in the drinking water due to the flooded state of the river." On account of my condemnation of the water supplied during the month of December, 1898, in my report for that month, in which I stated that the samples of water supplied by both the companies (Grand Junction and Chelsea) were, according to Mr. Cassal's analysis, of "decidedly inferior quality," both of the companies wrote letters on the subject, forwarding with them reports by Professor Sir Edward Frankland and by Sir William Crookes and Professor Dewar, on which I prepared the following report:—

"With regard to the letters from the water companies, on which you have asked me to report to you, I find that the reports sent with them confirm my opinion of the inferior quality of the samples of water supplied in December as deduced from the results of the analyses made by your public analyst, Mr. Cassal.

"Thus Professor Sir Edward Frankland, in his report, referring to the Thames companies, says, that 'owing to heavy floods and insufficient storage the water sent out by all the companies, except the West Middlesex, *contained an excess of organic matter* which was, however, almost entirely of vegetable origin' (the italics are mine). It is true that he says it 'was in every case efficiently filtered before delivery,' but this means that it contained no notable quantity of suspended matters and neither did Mr. Cassal's analyses show any excess of such matters.

"Sir William Crookes and Professor Dewar, in their report, make no remark on the amount of organic matter beyond stating that 'the purity of the water in respect to organic matter has been determined by the oxygen and combustion processes.' From the results of their analyses, as shown in their tables, I find that the 'oxygen required to oxidise the organic matter' averaged for the Grand Junction Company 0·071 of a grain per gallon, and for the Chelsea Company 0·063 of a grain per gallon whereas in the month of September last it averaged only 0·025 for each company; in other words, the amount of 'oxygen required to oxidise the organic matter' was for the Grand Junction Company nearly three times as much, and for the Chelsea Company two-and-a half times as much as that required in September.

Dr Graham's theory and have passed various opinions as to its validity Dr. Graham states that the red blood corpuscles of individuals stricken with dengue contain a parasite resembling the plasmodium malariæ, with this difference, that its cycle of production is much longer than is that of the malarial parasite In a series of experiments conducted by Dr Graham he obtained positive and negative results just as mosquitoes were and were not allowed to bite infected persons. He therefore drew the conclusion that dengue is not contagious, but like malaria the disease is carried by certain forms of culex from person to person.

Improvement in Market Milk

Mr R. A. Pearson of the United States Department of Agriculture has recently issued a pamphlet in which are set forth suggestions for the improvement of market milk. Mr. Pearson suggests that a milk commission should be formed consisting of a responsible body of citizens who are interested in an improved milk-supply The commission should select and secure the advice and assistance of four experts—a veterinarian, a physician, a bacteriologist, and a chemist—all more or less familiar with the conditions and possibilities on dairy farms. The commission should send to each dairyman who supplies milk to the city a circular naming all the particular conditions which should be found on every farm where milk is produced for city use and announcing that when any dairyman notifies the commission that he is fully conforming to the conditions specified, or endeavouring to do so, his dairy will be inspected, and if it is found to comply in letter and spirit to all the requirements his name will be placed on an "approved" list and he will receive an official endorsement in the form of a certificate testifying that the milk furnished by him has been thoroughly examined and found to comply with the conditions recommended by the commission. Great and intelligent interest is now being taken by the inhabitants of the United States generally in the milk-supply Milk commissions are in existence in New York and in Philadelphia, the former under the auspices of the New York Medical Society and the latter under the direction of the Philadelphia Pediatric Society In both cities the plan has worked well and it is thought that if Mr Pearson's scheme were adopted in the cities and towns throughout the United States the effect, so far as a pure milk supply is concerned, would be most beneficial.

June 2nd

Obituary.

ROBERT WHITTINGTON LOWE, M D EDIN., M R.C.S ENG

WE regret to have to announce the death on June 9th, after an illness lasting for some months, of Dr Robert Whittington Lowe, late of the Army Medical Department. Dr Lowe received his medical education at Edinburgh University, where he graduated as M D in 1863, becoming M.R.C.S in the same year After holding the post of resident medical officer to the St. Marylebone Infirmary, Dr Lowe, on the recommendation of Mr Syme, made an extensive tour abroad, accompanying a patient to Italy, Egypt, and Turkey On his return he entered the Army Medical Service and served as surgeon to the 5th Dragoons. He was for some time in India, serving chiefly in the Bombay Presidency, where he held the post of physician to the Rajah of Sundoor He was also Government medical officer during the cholera epidemic of 1872. In the Ashanti expedition of 1873-1874 he volunteered for active service and took charge of Sir William Butler's expedition, being mentioned in despatches and receiving the medal and clasp for Kumasi.

WEST HAM HOSPITAL, STRATFORD, E —For Saturday, June 21st, the staff of this hospital are arranging an "At Home." Mr Alfred Capper, the thought reader, has consented to help in the entertainment and a number of friends, amateur and professional, will do their best to provide for the amusement of the patients, the staff, and the guests A collection will be made in aid of the funds for the coronation festivities Any donations will be thankfully received by the secretary on behalf of the committee.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

THE General Medical Council concluded its seventy-fourth session on Tuesday afternoon, June 3rd The proceedings of the Council on that day are reported in this issue of THE LANCET

On Friday, May 30th, the time of the Council was wholly occupied by a discussion of methods for the readjustment of the financial relations of the Council and Branch Councils. The Financial Relations Committee, appointed a year ago to consider the whole financial position of the Council, presented an interesting and suggestive report which, as well as the debate thereon, must have opened the eyes of the Council to the veritable state of its pecuniary affairs. Additional attention was drawn to the question by the report of the Finance Committee of the Council which came up for consideration on the following day and which showed certain unpromising tendencies towards increase of expenses and decrease of receipts. The result of a consideration of this report was the suspension of payments to the sinking fund.

On Monday, June 2nd, a report of the Public Health Committee led to a practical discussion of the training required for Public Health Diplomas which was continued on the last day of the sitting

The unfortunate subject of the Midwives Bill was also touched upon on Tuesday. The views of the General Medical Council with regard to this Bill have been absolutely ignored and the Direct Representatives have been unable to assist the profession at large to resist a measure which is in several directions a retrograde one even though certain reforms which it aims at effecting are admittedly for the public good

The session was a quiet one, its most distinguishing feature being the general recognition by the Council that its financial affairs required setting in order

TUESDAY, JUNE 3RD

THE Council met again to-day, Sir WILLIAM TURNER presiding

The Prevention of Personation.

The Council went into Committee for the further consideration of the following motion by Mr Horsley arising out of the report of the Committee on the Prevention of Personation viz. —

> All applications for restoration to the Medical or Dentists Register or for registration under exceptional circumstances in these registers shall be accompanied by a statutory declaration and shall be drawn in the terms stated in the forms included in schedules 6a 6b, 6c, 6d"

Mr HORSLEY explained that if the Council approved of this regulation proposed by the committee it would conclude the regulations about which there had been any dispute In their report the committee indicated that there were several minor matters which required settlement Among these there was a difference between the Medical Act and the Dentist Act. Under the latter Act when a man's name lapsed from the Register, not by reason of his own fault, but because of change of address or some such cause, the Registrar was empowered to write to him by registered letter to inquire as to the circumstances and this amount of liberty was not given under the Medical Act. The committee thought that if this power were extended to the Medical Act it would secure greater accuracy in the Medical Register He would suggest that after disposing of his motion the Council should not go further at present but leave the committee to bring up a document setting out clearly all the proposed changes in order that the Council might deal with them next session as a whole.

Mr. BROWN urged Mr. Horsley not to press his motion on the present occasion because he did not think that the Council was quite convinced of the practicability of the proposals made. For himself he saw great difficulty with regard to the identification of practitioners.

Dr. MACALISTER thought that the Council should decide this question now because it was cardinal and if it was carried much would follow consequentially. For the information of the Council he would read the following extract from the comments of Mr. H. E. Allen, the Registrar, viz.:—

> I am of opinion that in the interests of practitioners whose names have been removed from the Register for the trifling omission of not keeping the office properly advised as to their addresses, they should not have the path back to the Register made too difficult. The absence of a man's name from the Register frequently only becomes known to him at the last moment when he is intending to take up an appointment, or to certify a death, or to give medical evidence, and time may not allow for the obtaining of a certificate of identity signed by two medical practitioners or by two magistrates. Above all, I would respectfully submit that it is most important that the delegation of power to the branch registrars to restore names and report their action to the Executive Committee, which was found necessary in 1887, should be retained, seeing that if a meeting of the committee is to be waited for the unfortunate practitioner might be penalised by being retained in the category of illegal practitioners for an unnecessary period of some months.

Mr. HORSLEY pointed out that the Scottish Registrar did not see any objection to the proposed change, while the Irish Registrar only partly felt the difficulty.

On a division the proposed regulation was carried by 12 against 5 votes.

The Council then resumed.

Mr. HORSLEY moved—

> That the Prevention of Personation Committee shall prepare for the November session a complete report on the whole subject and submit a series of recommendations on which the decision of the Council may be taken and that the report be in the hands of members of Council a fortnight before the meeting.

This motion was agreed to and Dr. Finlay was appointed to the committee in the room of Dr. Reid.

Diplomas in Public Health.

Prints of the resolutions and rules for Diplomas in Public Health as amended at the previous day's sitting having been circulated,

Dr. MACALISTER proposed their adoption.

Mr. TICHBORNE seconded.

Dr. NORMAN MOORE said that before these resolutions and rules were finally passed he wanted to say a few more words about Clause 4 which on Monday had been adopted or rather readopted in the following terms:—

> Every candidate shall have produced evidence that, after obtaining a registrable qualification, he has attended during three months the practice of a hospital for infectious diseases at which opportunities are afforded for the study of methods of administration.

He thought the Council had been under a slight degree of misapprehension in thinking that every effort had not been made to get leave for instruction in sanitary subjects in the metropolitan hospitals. Every effort had been made—unsuccessfully; and if this Clause 4 was passed as one of the rules it would put a stop, so long as it was in force, to candidates for the Public Health Diploma obtaining the necessary facilities for instruction in London. He held in his hand a letter received from the secretary of the Metropolitan Asylums Board on Jan 18th last, which stated that the Board had no authority to afford anything beyond medical instruction in their hospitals and at all events the arrangements there did not permit, under the present circumstances, the requirements of the General Medical Council in regard to public health instruction being carried out. Of course, the Council had the power to decree what they liked, but although this applied to London only it was of the very greatest importance in London; and he ventured to take up a little of the time of the Council in order to propose an addition to Clause 4, which would make it workable in London He could assure them that the English Royal Colleges were anxious to have the Council's Public Health Diploma regulations carried out in the fullest possible way, but they certainly thought that Regulation 4 was unworkable and they would simply be obliged to decline Diplomas in Public Health if that regulation remained as it was at present. What he proposed to add was this note:—

> The study of the methods of administration shall include the methods of dealing with patients at their admission and discharge as well as in the wards of the hospital.

That was to say, that the two points concerned with sanitary administration—namely, (1) admission and discharge of patients and (2) disinfection—must be studied, or the instruction would not be recognised. That would be the minimum studies. It was feared that something relating to accounts might be put into the regulations by bodies entitled to grant Public Health Diplomas, but under his proposal such studies would not be required. If such a note as he proposed was added he wished to emphasise this—that it would make Clause 4 workable in London; if the regulation stood alone it would absolutely prevent the English Royal Colleges from granting diplomas.

Dr. BENNETT seconded the proposal.

Mr. BROWN questioned whether every effort had been made to induce the London Fever Hospital to give the necessary facilities which it was quite capable of doing

Sir HECTOR CAMERON did not think it had ever been in the mind of the committee that investigating accounts of the hospitals was to form part of the instruction of administration. He thought that what they had in mind when framing the regulation was a necessary proportion of nurses, the serving of food, the question of what was to be done with the bed and bedding, and other such things, all of which really were embraced in the proposal submitted by Dr. Moore to the Council.

Dr. MACALISTER did not intend to oppose the proposal, for he believed it contained the gist of the whole matter. The matters involved under Dr. Moore's two points were those which candidates should know about before they were given diplomas. The matter of the accounts of an institution should be left to the managers of it. He had heard nothing to make him think that if the Metropolitan Asylums Board had the thing put clearly before them they would not give the facilities desired.

Dr. MCVAIL hoped the Council would not depart from the decision they so distinctly came to on the previous day in connexion with Clause 4. What was wanted was that before a man began work in a certain locality he should know everything about the administration of the hospital in that locality and he did not see why such a requirement should be modified for the sake of London. If there was to be modification there should be two classes of diploma, a London and an Imperial.

Sir CHRISTOPHER NIXON said it seemed to him that Dr. Moore's proposal did not alter Clause 4. It simply called particular attention to what would be required to be certified to. It simply specified that candidates should include in their studies the matter of the admission and removal of patients from the hospital and disinfection rendered needful by their presence in it. There was no attempt whatever to get rid of the requirements laid down in Clause 4.

Dr. PAYNE suggested that Dr. Moore might include the words "and generally the duties of a medical superintendent of such an hospital."

Dr. MOORE willingly consented to accept Dr. Payne's suggestion.

After Mr. BROWN had informed the President that the London Fever Hospital was not under the charge of the Asylums Board, after Mr. BALL had expressed the hope that the regulation would be left unaltered, and after Sir WILLIAM THOMSON had stated it to be his opinion that one of the most important matters of administration was the financial cost of running a hospital, of treating each patient therein, &c., the Council decided to vote on the proposed note formulated as follows:—

> Methods of administration shall include the methods of dealing with patients at their admission and discharge as well as in the wards and medical superintendence of the hospital generally.

This proposal was carried by 15 votes to 5; five members did not vote, while six were absent.

Dr. MCVAIL moved that the resolution which had just been agreed to should be referred to the Public Health Committee for their consideration and report to next meeting of Council. He urged that the reasons why this motion of his should be accepted were very strong. The chairman of the Public Health Committee (Dr. Bruce), who had had to leave for Scotland, and Mr. Power, the successor of Sir Richard Thorne, were not here; no objection had been taken to the regulation by the deputation of teachers on Public Health, and it was a regulation which had been framed with the greatest care and after much consideration and had been carried by a large majority of the Council. He did not see that the vote of 15 out of 31 members to-day should upset what had been so carefully decided upon, especially as some of these 15 were new members and were unaware of the long and troublesome deliberations which had taken place before the regulation was adopted. The regulations of which they began consideration on the previous day had been in force only since January last. Were the Council going to change its regulations every six months or so? Were they going to change these because of some difficulty in one given locality?

Mr. BALL seconded the motion.

Dr. MOORE said the proposition which had been adopted was not a change, it was an interpretation; and every licensing body was at liberty to add as much as it liked to it. In putting forward the proposition he thought he was not interfering with any previous decision of the Council in any way. He simply wished to have the regulation put into workable form.

Mr. BROWN maintained that there was a change involved of a kind so vital that it should not be made so near the end of the session. It was done obviously because of the attitude one board assumed towards the Council's requirements, but, as he had pointed out, London was not absolutely dependent on that board and the facilities which the Metropolitan Asylums Board would not give might be obtained in the London Fever Hospital.

On a division 7 voted for the motion and 14 against it; 4 members did not vote and 6 were absent.

Dr. MACALISTER then moved that the resolutions and rules for Diplomas in Public Health as amended should come into force from this day (June 3rd).

Dr. MOORE seconded and the motion was agreed to by 17 votes to 6; 2 members did not vote and 6 were absent.

The Preliminary Examination.

On the motion of Sir JOHN BATTY TUKE, seconded by Dr. MACALISTER, the following report by the Education Committee was received and entered on the minutes:—

The Education Committee have considered the following correspondence, referred to them by the Executive Committee on May 28th, 1902:—

(a)

"54, George-square, Edinburgh.
April 14th, 1902.

DEAR SIR,—In the regulations of the General Medical Council students of the Scottish universities are permitted to pass their preliminary examination in two parts, but students taking the preliminary examination of the Educational Institute of Scotland must pass all the subjects at one time.

Students are also permitted now to take the lower grade leaving certificates in two parts.

Will you please inform me whether candidates may, under these regulations,

(1) Pass a part of the subjects at the universities and the remaining part at the Educational Institute of Scotland, or

(2) Pass a part of the subjects at the leaving certificate examination and the remaining part at the Institute?

The question is one of construction, and it appears to this board that if the part of the university examination or the leaving certificate examination is considered to be of a standard that exempts the student from further examination in proceeding to university examinations there is no reason why students presenting themselves for the Institute's examination should be asked to repeat subjects passed (presumably) on that higher standard.

The board are also of opinion that it is easier for a candidate to attempt a university examination and pass in part and be allowed to try the remainder as often as he thinks fit than to be required to repeat all the subjects at the institute's examination at each appearance.

Yours faithfully,
JAMES ROBERTSON.

H. E. Allen, Esq., Registrar,
General Medical Council."

(b)

"General Medical Council Office,
299, Oxford-street, London, W.,
April 15th, 1902.

DEAR SIR,—In answer to your letter of the 14th instant I have to state (1) that a candidate for registration cannot pass part of his preliminary examination at one of the Scottish universities and the *remaining* part at the Educational Institute of Scotland; nor (2) can he pass part of the required subjects at the leaving certificate examination and the remaining part at the Institute.

The examination of the Educational Institute of Scotland is considered by this Council to be a junior examination and cannot be accepted unless it is complete *in itself*.

On the other hand, the lower grade leaving certificates of the Scotch Education Department are considered to be of a higher standard than the junior examinations recognised by the Council; hence the required subjects may be passed at two examinations. The first class certificates of the College of Preceptors are in the same category.

Yours faithfully,
H. E. ALLEN.

J. Robertson, Esq."

(c)

"54, George-square, Edinburgh.
April 16th, 1902.

DEAR SIR,—I am favoured with your letter of yesterday and will be obliged by your bringing the queries in my letter of 14th inst. before the next meeting of the General Medical Council.

If the General Medical Council considers the Educational Institute of Scotland's preliminary examination to be a junior one, and the examinations of the Scottish universities and of the lower grade leaving certificates to be of a higher standard, this board sees no reason why students who have passed subjects on that higher standard should be required to pass them again in the junior examination.

Yours faithfully,
JAMES ROBERTSON.

H. E. Allen, Esq."

It will be remembered that on Nov. 30th, 1901, the Council approved a report of the Education Committee in which it was stated that, along with two other examinations, the preliminary examination of the Educational Institute of Scotland was recognised for the year 1902 as an examination in which all the required subjects are to be passed at one time. Certain improvements in the examination had been proposed by the institute and the report proceeded: "When the committee have had further experience of the precise standard demanded by the examiners, and the general working of the examinations, they will be in a position to report whether any further modifications are desirable."

Apart from the question, whether in any case it is desirable to encourage students to pass their preliminary examinations in piecemeal *fashion before different educational bodies, the committee feel* that they are not yet in a position to report that the institute's examination is equivalent in scope and standard to the lower grade leaving certificate examinations.

They are of opinion that the answer forwarded to Mr. Robertson by the Registrar correctly expresses the purport of the Council's regulations and they have at present no information which would justify them in proposing that the regulations should be modified in the direction suggested in Mr. Robertson's letters.

Sir JOHN BATTY TUKE consulted the Council in regard to the reply to the deputation from the council of the British Medical Association who on Saturday last had had an interview with the Education Committee on the subject of the standard of the preliminary examination in general education. The deputation's arguments, he remarked, had covered a great deal of ground and it was impossible to give them an answer on the spot. He had undertaken to send a reply as soon as possible and what he proposed to do was to draft a report to be sent in the first place to each member of the Education Committee for their remarks. But he wished to know if it would be necessary to send that report to each member of the council before it was forwarded to the *deputation*.

After some conversation it was agreed to leave the matter entirely in the hands of the Education Committee.

The British Pharmacopœia.

On the motion of Dr. MACALISTER, seconded by Dr. PAYNE, the following report of the Pharmacopœia Committee was received and entered on the minutes.

The Pharmacopœia Committee have to report that up to the present date 32,068 copies of the British Pharmacopœia 1898, and 354 copies of the Indian and Colonial Addendum 1900, have been disposed of.

The Government of *India edition of the Addendum*, authorised by the Council on Dec. 3rd, 1901, was prepared for the press by the Chairman and published by direction of the Executive Committee on Feb. 28th, 1902 (Minutes, vol. xxxix., pp. 42, 43). Of this edition the 3500 copies ordered by the Indian Government have been delivered and paid for, and 112 other copies have been disposed of.

As the stock of the British Pharmacopœia, 1898, now in hand is reduced to 440 copies, the committee recommend that the President should be authorised to direct the preparation during the summer of a further issue of 1500 copies.

Since the last report of the committee two meetings of the Conference with Representatives of the Pharmaceutical Societies of Great Britain and of Ireland have been held, at which useful discussions have taken place as to the preliminary researches which are necessary in preparation for the next Pharmacopœia. The conference has also had before it a series of reports containing the results of a minute and exhaustive inquiry into the solubilities of the chemical substances included in the Pharmacopœia. This inquiry has been conducted by Professor Greenish under the direction of the Research Committee of the Pharmaceutical Society of Great Britain in the laboratories of the society. In order to ascertain the purity of the drugs under examination it has been necessary to scrutinise afresh the chemical tests given for them in the Pharmacopœia. This scrutiny has led to suggestions for the improvement of these tests which promise to be of great value in relation to pharmaceutical chemistry and will certainly call for the fullest consideration in the revision of the Pharmacopœia. Similar researches are in progress in relation to the percentage of ash which should be yielded by good specimens of the official vegetable drugs, and here again collateral inquiries have been instituted bearing on the identification of the vegetable drugs and of their powders.

Methodical and laborious inquiries of the above nature cannot be carried on without incurring considerable expense and the committee understand from the representatives of the Pharmaceutical Society of Great Britain that in this case the cost has been unexpectedly heavy. The committee highly appreciate the service rendered by the society and its officers to pharmaceutical science in general and to the revision of the Pharmacopœia in particular; and they desire to express their appreciation by recommending that a grant of £100 be made to the society as a contribution towards the expense incurred by it in carrying on these valuable investigations.

The committee are further of opinion that it is desirable that a digest of the criticisms and researches bearing on the Pharmacopœia which have been published from 1875 to the present time should be procured, and they recommend that the sum of £50 be placed at the disposal of the committee for this purpose.

The recommendations contained in this report were adopted. They were (1) that the President direct a further issue of 1500 copies of the Pharmacopœia; (2) that a grant of £100 be made to the Pharmaceutical Society of Great Britain towards the expense incurred by it in special investigations carried on to assist in the preparation of the Pharmacopœia; and (3) that £50 be placed at the disposal of the committee to pay for a digest of the criticisms and researches bearing on the Pharmacopœia which have been published from 1898 to June 1st.

The Midwives Bill.

Sir JOHN WILLIAMS, seconded by Mr. BROWN, moved that the following report of the Midwives Bill Committee be received and entered on the minutes:—

The committee submit to the Council as its report the resolutions at which it arrived on March 10th, as embodied in the following minutes of the sitting:—

MONDAY, MARCH 10TH, 1902.

Present: Sir John Williams (in the chair), Mr. Horsley, Mr. Brown.
H. E. Allen, Registrar.

1. Sir John Williams, at the request of the committee, took the chair.

2. Read: The request made by the General Council on Tuesday, Feb. 25th, 1902, viz.:—

"That in the event of the Midwives Bill, at present before the House of Commons, passing the second reading Sir John Tuke be requested to communicate the resolutions of the Council on the subject to the Grand Committee on Law."

3. Clauses 1 and 2 of the Council's resolutions were adhered to and after discussion it was resolved:—

"(3) That any measure which proposes merely to protect the title of 'midwife,' however defined, and does not make illegal and penal the unlicensed practice of midwifery for gain, cannot be regarded as offering a sufficient safeguard in the interest of the public health in the present Bill."

4. Clause 3 of the Bill was then considered and it was agreed to leave out the words on page 2, lines 4 and 5, from "from" to "certificate."

5. After discussion it was carried that the words "Incorporated Midwives' Institute" should be omitted and "Royal British Nurses" be substituted in Clause 4.

6. In Sub-section 2 of Clause 4 it was carried that Sir John Tuke be requested to press for the omission of the word "persons" and the substitution of the words "registered medical practitioners."

7. In line 31 of the same clause it was agreed to press for the omission of the words "the Privy Council after consultation with."

8. In Clause 10, pp. 5 and 6, it was agreed to press for the omission of the first two paragraphs in favour of the following amendment of which Sir John Tuke had given notice.—

"No woman shall hold herself out as a practising midwife in any county or county borough without having previously obtained from the local supervising authority a licence enabling her to practise therein, which licence shall be granted on proof by the woman that her name is on the midwives' roll. The licence shall remain in force till the 31st day of December following and shall be revocable at any time by the local supervising authority in case the holder be proved to the satisfaction of the Central Midwives' Board to have infringed any of the regulations framed under this Act. The licence shall be issued on payment of a fee of 1s, it shall only be available in the county in which it is issued, and it shall be renewed annually on the first day of January."

9. It was agreed that Sir John Tuke should be requested to press for the insertion in the present Bill of Clause 9 in the Bill of 1898, which provided for the appointment of medical officers of health as the local supervising authorities. (See Bill in Minutes, vol. xxxv., p. 30.)

10. Amendments of which Dr. Ambrose, M.P., had given notice were considered. So far as they did not cover the same points as those provided for in Sir John Tuke's amendments it was agreed to leave them in his hands.

Then committee then adjourned. JOHN WILLIAMS.

The motion was agreed to.

Dr. MACALISTER said that there had been no motion made for the approval of the report. If there had been he should have opposed it because so far as Section 5 of the report was concerned it went beyond the instructions which the committee had received.

Mr. JACKSON moved the approval of the report omitting Section 5.

Mr. BRYANT seconded.

Dr. MACALISTER thought that perhaps after all there was no use in passing this motion, for the report was now on the minutes and such as it was it might be allowed to stand.

On a division the motion was supported by only three votes and was declared to be lost.

Mr. BROWN moved—

That in the opinion of this Council the Midwives Bill, as amended by the House of Commons' Grand Committee on Law, does not contain the safeguards necessary to protect the public against the practice of midwifery by ignorant and incompetent persons.

The PRESIDENT pointed out that the Council had already passed a resolution to the same effect and, as the report of the Midwives' Bill Committee just placed on the minutes showed, in almost the same words. Was it necessary to go further?

Mr. BROWN considered it necessary in the interests of the profession and the public that the Bill should not go further without a strong representation being made by the Council as to its inadequacy and the harm rather than good that it would do if passed. It was a duty incumbent on the Council to repeat at this time, or pass in even stronger terms, any similar representation they had made.

The PRESIDENT explained that the Privy Council had been informed of the views the Council held as to the Bill. The only change since made was that it had been provided that before the rules for the Midwives Board were adopted the General Medical Council were to be consulted in regard to them.

Mr. BROWN wished to press his motion.

Mr. JACKSON seconded it.

Sir WILLIAM GAIRDNER thought the Council should have nothing further to do with the Bill because of the way in which the Council's views had been ignored. His opinion was expressed in the following words, which he proposed to ask the Council to accept as a finding, viz.:—

That in consideration of the fact that the Midwives Bill at present in Parliament, as amended by the Grand Committee of the House of Commons on Law, &c., does not in any respect embody the principles unanimously adopted by the General Medical Council on April 6th, 1898, and directed to be forwarded to the Lord President of the Privy Council, the General Medical Council hereby resolves that it would not be in the public interest that the latter part of Clause 4 of the Bill should remain a part of the statute in the event of its passing the remaining stages in the House of Commons.

The PRESIDENT asked if this was to be an amendment to Mr. Brown's motion.

Sir WILLIAM GAIRDNER replied that it was not an amendment. It was a proposal to be taken after Mr. Brown's was disposed of.

On a vote Mr. Brown's motion was carried by 13 votes to 5.

Sir William Gairdner's proposition was then considered.

The PRESIDENT pointed out that it raised an absolutely new question.

Mr. BROWN: Of which notice ought to have been given.

The PRESIDENT: Is the proposal seconded? (After a pause): If there is no seconder the proposal falls.

The subject dropped.

The Birmingham Dental Degree.

Mr. BRYANT, as chairman of the Dental Education and Examination Committee, submitted the following report:—

The Dental Education and Examination Committee report that they recommend that, as an application has now been made by Mr. Harold Round, Lic. Den. Surg. R. Coll. Surg. Eng., May, 1900, for the registration of his degree of Bachelor of Dental Surgery of the University of Birmingham, dated July 6th, 1901, the General Council should make an order for the registration in the Dentists Register of the degree of Bachelor of Dental Surgery of the University of Birmingham as an additional diploma granted in respect of a higher degree of knowledge than is required to obtain a certificate of fitness under the Act (Sec. xi. 6 of the Dentists Act, 1878).

In moving that this report be received and entered on the minutes and that the recommenation it contained be adopted Mr. Bryant reminded the Council that Birmingham gave degrees only to the already qualified. A high measure of knowledge was necessary before it could be obtained; it, in fact, was an honours degree and he thought that the Council should therefore have no hesitation in recognising it.

Mr. TOMES seconded and the motion was adopted.

A Protest from Scotland.

On the motion of Dr. MACALISTER the following correspondence addressed to the Scottish Branch Council and referred by that Branch to the General Council was received and entered on the minutes:—

The Glasgow Southern Medical Society,
1, Berlin terrace, Pollokshields,
Glasgow, April 18th, 1902.

DEAR SIR,—I inclose a formal protest from the above society against the edict recently issued by the General Medical Council.

I am, yours truly,
JOHN FRASER ORR, M.D., Secretary.

James Robertson, Esq.,
Registrar of Scottish Branch of the General
Council of Medical Education and Registration.

The Glasgow Southern Medical Society,
Glasgow, April 18th, 1902.

JAMES ROBERTSON, Esq.
Registrar of Scottish Branch of the General Council of Medical Education and Registration.

SIR,—We, the undersigned, in name and on behalf of the Glasgow Southern Medical Society, hereby protest against the notice of the General Medical Council to registered medical practitioners published in the *Glasgow Herald* of 14th December, 1901, as being unwarrantable, oppressive, and vexatious

Signed on behalf of the Glasgow Southern Medical Society.

JOHN STEWART, President.
D. MACGILVRAY, Vice-President.
THOS. FORREST, Treasurer.
JOHN FRASER ORR, Secretary.
AND. WAUCHOPE.
JAMES FORRESTER.
LACHLAN BURGES.

[COPY]

64, George-square, Edinburgh,
April 22nd, 1902.

DEAR SIR,—I have to acknowledge receipt of your letter of 18th inst. and the formal protest therein specified, which I will submit to the first meeting of the Scottish Branch Medical Council.

Yours faithfully,
(Signed) JAMES ROBERTSON

John Fraser Orr, Esq , M.D ,
Secretary, The Glasgow Southern Medical Society,
1 Berlin terrace, Pollokshields, Glasgow

Dr MACALISTER said that so far as he could ascertain the Scottish Branch Council made no comments. They had simply sent the correspondence to the General Council

Mr BROWN I second the motion that it be entered on the minutes, but should a copy of the "edict" not accompany it?

Dr MACALISTER thought not. They could only guess that the "edict" was one of the official notices issued by the Council as an advertisement.

The General Registrar

Mr H. E ALLEN was reappointed Registrar to the Council The appointment of Registrar is an annual one and by standing orders requires to be made at the termination of the business of the May session.

Thanks to the President

Mr BRYANT I think we all should like to return thanks to our President for the careful way in which he has conducted the business of the session.

Sir CHRISTOPHER NIXON I second that, and must acknowledge the great consideration you, sir, have always shown to the members of the Council.

Sir WILLIAM TURNER Thank you, gentlemen.

The minutes of the sitting were then read and confirmed and the Council rose till November next.

Medical News.

UNIVERSITY OF CAMBRIDGE —The following medical degrees were conferred on June 5th —

Doctor of Medicine —H A. Gaitskell Clare; H. F Panker, Emmanuel, W J Lindsay, Sidney; R. J Reece, Downing; and J A. Wright non-collegiate.

Bachelor of Medicine.—H. I Claxton, King's; J A. Andrews (and B C.), St. John's; E. R. Clarke, St. John's; A P. Laycock (and B.C), St John's; R Rolfe, Clare; C H Glenn Pembroke; B B Sapwell (and B.C) Corpus Christi; H. O Butler, Emmanuel

Bachelor of Surgery —J F Alexander, Trinity; C de C Pellier, Clare.

UNIVERSITY OF LONDON: FACULTY OF MEDICINE —A meeting of the Faculty of Medicine was held on June 6th at the University, Mr H. T Butlin, the Dean of the Faculty, presiding A report from the committee on the proposed Institute of Preliminary and Intermediate Medical Sciences was received and adopted without dissent. The report was in the nature of a reply to the Senate in response to a request that it should be furnished with information as to the capital outlay, the annual cost of maintenance, and the accommodation and staff necessary for the proposed Institute of Medical Sciences, with suggestions for the administration of the institute. The committee had dealt with all these points and submitted two alternative schemes for staffing the institute and remunerating the teachers—one which they regarded as the ideal if funds were available and the other which was feasible if no other source than students' fees were forthcoming for the maintenance of the institute. The report also made some recommendations as to the site of the institute and concluded by urging the Senate "to make the provision of the proposed Institute of Medical Sciences one of the chief items in the public appeal for funds shortly to be issued by the University" The Faculty also considered the regulations proposed by the Board of Advanced Medical Studies for the Degrees of M.B. and B.S The three most important changes proposed by the board are as follows —

(a) The M.B., B.S examination shall be united so as to form a single entrance to those degrees both of which shall be conferred on each successful candidate

(b) No separate examination shall be held for honours

(c) The subject of examination may be divided into two groups one of which shall comprise surgery and midwifery and diseases of women and the other medicine pathology forensic medicine and hygiene Either group may be taken first at the option of the candidate or the groups may be taken together

These three proposals were allowed to be sent to the Senate without comment from the Faculty Some other proposals of the Board of Advanced Studies aroused a good deal of discussion, more particularly the large number of compulsory lectures required and the shortness of the period of clinical study On these and some other points the Faculty passed definite resolutions to be forwarded to the Senate. The consideration of the proposed regulations for the M S and M.D degrees was adjourned till the next meeting of the Faculty on Friday, June 20th, at 5 P M , at the University

BARKER ANATOMICAL PRIZE.—This prize, which is given by the Royal College of Surgeons in Ireland, is of the value of £21 and is open to any student whose name is on the anatomical class list of any school in the United Kingdom. The prize for 1903 is offered for the best dissection of the sole of the foot and preparations must be placed in charge of the curator of the museums of the Royal College of Surgeons in Ireland before March 31st in that year Further particulars may be obtained from Mr Arthur H White, curator of the museums, Royal College of Surgeons in Ireland, Dublin.

FREEMASONRY —At the quarterly communication of the United Grand Lodge of England held on June 4th at Freemasons' Hall, London, certain appointments to office in Grand Lodge made by the M W Grand Master in view of the Coronation of His Majesty King Edward VII. were announced. They included the following names T G A. Burns, M A. Oxon., M R.C S Eng , W Wynn Westcott, M B. Lond , M R.C.S Eng , C. Vincent Cotterell, L.D S R.C S I., as Past Junior Grand Deacons , J Beresford Ryley, M D Brux., M.R.C.S. Eng , as Past Deputy Grand Director of Ceremonies , and R. J Maitland Coffin, F R.C.P Edin , and A. G Sandberg, M.D Vermont, L.R.C P & S. Edin., as Past Assistant Grand Directors of Ceremonies

THE ST JOHN AMBULANCE BRIGADE MEMORIAL.—On June 11th the Prince of Wales, Grand Prior of the Order of St. John of Jerusalem in England, unveiled at the Church of St. John, Clerkenwell, the memorial tablet which has been erected there to the memory of members of the St. John Ambulance Brigade who have died while on service in South Africa. Many distinguished members of the Order were present at the ceremony The tablet is inlaid with mosaic and above the names the figure of an angel bears a shield with the arms of the Order. On the centre panel appears the following inscription . "To the Glory of God, and in memory of those members of the St. John Ambulance Brigade who died of disease contracted while engaged in attendance on the sick and wounded during the South African campaign, 1900-1902. Erected by His Majesty King Edward VII., Sovereign head and patron, H.R.H. the Prince of Wales, Grand Prior, and the Chapter-General of the Grand Priory of the Order of the Hospital of St. John of Jerusalem in England "

SOCIETY FOR THE PREVENTION AND CURE OF CONSUMPTION IN THE COUNTY OF DURHAM.—The annual meeting of this society was held on June 11th in the town-hall, Sunderland, when the report of the general committee was read From this report we extract the following passages —

> As regards the prevention of consumption your committee have tried to teach the public that the disease is communicable and have urged the sanitary authorities of the county to take steps to stop its ravages Over 2000 copies of the society's pamphlet, 'Consumption: its Prevention and Cure,' in addition to other literature on the subject have been sent to nearly every member of the 40 sanitary authorities as well as to others; addresses have been given to meetings of workmen, members of the Sunderland Board of Guardians and the Co-operative Society and letters have been sent to the various local authorities asking them to adopt preventive measures. Several authorities now offer the free disinfection of rooms vacated by consumptives and distribute leaflets showing the great danger of indiscriminate spitting, of breathing close and vitiated air, and the need for the better ventilation and lighting of cow byres as well as the more stringent supervision of the milk-supply Voluntary notification of cases of consumption has been in force in Sunderland for a year and the medical officer of health states that 96 cases have been reported and that much good has been done by the information affording opportunities for instructing the patients and their friends in the steps necessary to prevent the spread of the disease, and nine of the cases obtained admission to the society's sanatorium. The Borough of Gateshead has also adopted voluntary notification so that this measure is now in force amongst over a quarter of a million of the population of the county ..... The Boroughs of Sunderland and Gateshead and the Durham County Council have arranged that medical practitioners may have suspected sputum examined for tubercle bacilli free of charge on application to the medical officer in each district During the year 55 cases were discharged after treatment in the sanatorium at Stanhope Of these 33 of the cases on admission had the lungs consolidated only but eight of these were complicated with pleurisy or laryngitis and seven others had extensive consolidation so that only 15 of the 55 had the disease in an early stage The

remaining 25 were found on admission to have the lungs broken down into cavities and were therefore advanced cases. Of the 30 consolidation cases 23 were enabled to return to work, 12 were apparently cured and left free from all signs of disease, 14 were much improved, and four were improved. Two of the four "improved" were complicated with other diseases and, after leaving, relapsed and died. The average stay of the 30 consolidation cases was 14·2 weeks and the average gain in weight was 1·25 pounds per week.

Money and offers of suitable employment for discharged patients are much needed.

Donations and Bequests.—By the will of Mr. Benjamin Buck Greene the Seamen's Hospital at Greenwich, the Homœopathic Hospital, the Royal Berkshire Hospital, and the Newbury District Hospital each receive £100.—By the will of Mr. Richard Ovey £500 are bequeathed to the Royal Berkshire Hospital, Reading.—By the will of Mr. George Fergusson Wilson £1000 are bequeathed to King's College Hospital and £1000 to the Royal Free Hospital.

Literary Intelligence.—We have received a copy of *Al-Tib Al-Hadisse*, a new medical review edited by Dr. A. Eid. The *Al-Tib Al-Hadisse* is the only Arabic periodical of the native medical man and chemist, so that its pages put the native practitioner in touch with international scientific discovery, especially with regard to such diseases as are prevalent in Egypt and other tropical lands.

Medical Magistrates.—Mr. Thomas Mather Querney, M.R.C.S. Eng., L.R.C.P. Lond., has been gazetted a justice of the peace for Port St. John, Pondoland.—The name of Dr. C. T. Brookhouse of Brockley, has been placed on the Commission of the Peace for the County of London.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Midwives Bill.

So far as the House of Commons is concerned the Midwives Bill has only one stage to pass—namely, the third reading—and that will be taken to-day (Friday, June 13th), the second and last day reserved for Bills promoted by private Members. The future of the Bill rests, however, with the Home Secretary. His speech during the report stage was strongly hostile to the amendment making it an offence for a woman who is not certified to practise as a midwife habitually and for gain, and when he allowed it to pass with the period of grace for women now in practice extended till 1910 he reserved to himself the right to consider the whole question. In the House of Lords it will be within his power either to have the amendment struck out or modified or to have the whole Bill rejected.

HOUSE OF COMMONS.

Thursday, June 5th.

The Small-pox Hospital at Hanworth.

Sir Frederick Dixon-Hartland asked the President of the Local Government Board with regard to the small-pox hospital that was being erected at Hanworth, Middlesex, and which the officers of his department had just inspected and stated that there was no fear of pollution provided that the cesspools on the site were emptied regularly and their contents were not allowed to overflow or soak away into the soil, whether, seeing the importance of the question, he would give instructions by which all refuse, solid or fluid, should be first treated with lime and afterwards burnt as a means of ensuring safety to the public.—Mr. Walter Long replied: As I stated on a previous occasion, I have no authority to interfere with regard to this hospital, as it is not proposed to defray the cost out of borrowed money. Hence I am not empowered to give instructions of the kind desired, but I will recommend the urban district council to take all necessary measures for the safe disposal of refuse from the building when it is used as a hospital.

The Treatment of Epileptics.

Mr. Norman asked the President of the Local Government Board whether he proposed to take any action, by legislation, by general order, or otherwise, to bring about the separation in workhouses of the epileptics of both sexes who for the greater part of the time were sane and well behaved from the hopeless and permanent imbeciles.—Mr. Walter Long replied: Section 24 of the Lunacy Act, 1890, requires that a person shall not be allowed to remain in a workhouse as a lunatic unless the medical officer certifies that the accommodation in the workhouse is sufficient for his proper care and treatment separate from the inmates of the workhouse who are not lunatics, except where his condition is such that it is not necessary for his convenience or that of the other inmates that he should be kept separate. It follows that any sane epileptic is required to be kept separate from the imbeciles unless the condition of the latter is such that their separation from other inmates is not necessary. It does not at present appear to me that fresh legislation on this subject is requisite. If it should be shown that further regulations are needed I should be ready to consider the matter.

Uncertified Deaths in the Scottish Highlands.

Mr. Weir asked the First Lord of the Treasury whether he was aware that of the deaths which occurred in the highland crofting counties last year no less than 1479 were uncertified; and would he consider the expediency of introducing legislation on the subject.—Mr. Balfour replied: The Government are aware of the facts mentioned in the question but no pledge can be given at the present time to introduce the necessary legislation.

Monday, June 9th.

Death under Chloroform.

Mr. Delany asked the Secretary of State for War whether he was aware that Charles Vernon Freer, a private in the Cape Mounted Specials, when recovering from a wound received at Tweebosch, died at the General Hospital, Kimberley, after being put under chloroform for the purpose of extracting teeth; whether he would order an inquiry into the circumstances of this man's death; whether he would state why his parents received no official notice of his death and why the friends of deceased at Kimberley were not permitted to see the remains or to attend the funeral; and whether compensation would be made to his parents for the loss sustained by his death.—Mr. Brodrick replied: The man died as stated in the question. As the verdict at the inquest was to the effect that "due care was observed by the professional men engaged in the operation and no blame attaches to either the surgeon or to the dentist," no inquiry appears necessary. I have no information regarding the notification of the death or the treatment of the friends of the deceased. No question of compensation arises.

Tuesday, June 10th.

The Sale of Butterine.

On the motion of Mr. Hanbury a Bill was introduced and read a first time to amend the Sale of Food and Drugs Acts, 1875 to 1899, with respect to the sale of butterine.

THE MIDWIVES BILL.

REPORT STAGE DEBATES: IMPORTANT MODIFICATION INTRODUCED.

On Friday, June 6th, the House of Commons devoted several hours to the consideration of the Midwives Bill as amended by the Grand Committee on Law.

Mr. T. P. O'Connor moved to insert the following new clause—viz.:

"Where a person whose name is entered on the roll of midwives has, either before or after the passing of this Act, and either before or after her name is so entered on the roll, been convicted either in His Majesty's dominions or elsewhere of an offence which if committed in England would be a felony or misdemeanour, or been guilty of any disgraceful conduct in her practice as a midwife, that person shall be liable to have her name erased from the roll. The Midwives' Board shall cause inquiry to be made into the case of a person alleged to be liable to have her name erased under this section, and on proof of such conviction or of such disgraceful conduct shall cause the name of such person to be erased from the roll."

Mr. Heywood Johnstone, who had charge of the Bill, said that if the hon. Member did not consider the words in Sub-section 5 of Clause 3 to be sufficient he (Mr. Johnstone) would be quite willing to accept the new clause. The sub-section he referred to said that among the powers and duties of the Central Midwives' Board should be the following: "To decide upon the removal from the roll of the name of any midwife for disobeying the rules and regulations from time to time laid down under this Act by the Central Midwives' Board or for other misconduct and also to decide upon the restoration to the roll of the name of any midwife." In his opinion these words did all that the hon. Member desired.

The new clause was accepted by the House.

Mr. Galloway moved to insert a new clause in these terms, viz.:—

"Every council of a county or of a county borough shall inspect or cause to be inspected from time to time any premises wherein any woman receives or proposes to receive as a midwife a pregnant or lying-in woman, and if such premises shall in the opinion of the council be fit for the reception of a pregnant or lying-in woman the council shall issue a certificate to that effect upon payment by the midwife of such fee as may be fixed by the council and shall enter such premises upon a register to be kept by the council. 2. Any woman, whether certified or licensed under this Act or not, who after the first day of January, one thousand nine hundred and three, shall receive as a midwife a pregnant or lying-in woman in premises which shall not have been certified by the county council or council of a county borough as fit for the reception of such a woman under the provisions of this Act shall be guilty of a misdemeanour and on conviction on indictment shall be liable at the discretion of the court to a fine not exceeding £10, or to imprisonment for any term not exceeding two months with or without hard labour, or to both fine and imprisonment, or on summary conviction to a fine not exceeding £10."

Mr. Heywood Johnstone said that he appreciated the object of the hon. Member and to a large extent sympathised with it, but the clause he had proposed went far beyond the scope of the Bill and he could not accept it. If the local authority had the power and the duty to exercise general supervision over all midwives practising in their district they would exercise that supervision over the woman's home just as much as over the woman herself and they would be able to see whether it was a fit and proper place for the reception of lying-in women.

Mr. T. P. O'Connor, speaking in support of the proposed new clause, urged that something must be done to meet the case of lying-in homes, some of which had become the source of the greatest public danger.

Sir Walter Foster said that if this Bill became law this question would have to be faced in some form. At present in these lying-in homes there was the guarantee of the presence of a registered medical man, but if this Bill became law these institutions would be officered and worked entirely by persons certified under the Bill, and he submitted that the guarantee under the Bill was inferior to the guarantee under the Medical Acts. The Bill created a new class of practitioners and one of the means by which these women would be able to carry on their practice of midwifery and reap profit would be by running private homes and private hospitals for lying-in women. That was a danger to society which ought to be guarded against in the Bill and it would be the duty of Parliament to pass some such legislation as the proposed new clause. He therefore supported it.

Dr. R. **FARQUHARSON** said that he quite appreciated the necessity for inspecting the lying in homes which had been referred to but as the proposed new clause was drawn he was afraid that it would apply to private houses.

Mr. **RITCHIE** said that when he saw this clause on the paper he thought it hardly came within the title of the Bill. It certainly did not deal with any matter which was germane to the main point in the Bill. As the clause was drafted it would apply to every private house, to the case of a lady who took a relative into her home for this particular purpose. As to the matter of lying-in homes he would undertake to consider it and to see whether in another place something could not be done to prevent houses being used for this purpose which were not fit to be so used.

Mr. **GALLOWAY** explained that he had no thought of including private houses and if the right hon. gentleman would undertake to put in some words in another place to deal with homes he would not press this clause.

Mr. **RITCHIE** said that he would consider the question with a view of seeing whether it could be done, but he had no command over the other House. The point would be considered; that was all he said.

Mr. **GALLOWAY** suggested that in the circumstances the proper course would be to insert the clause now and have it amended afterwards.

On a division being taken the clause was rejected by 98 votes against 63.

Mr. T. P. **O'CONNOR** moved to insert the following clause by way of substitute for Clause 9 in the Bill, viz.:—

"No woman shall hold herself out as a practising midwife in any county or county borough without having previously obtained from the local supervising authority a licence enabling her to practise therein, which licence shall be granted on proof by the woman that her name is on the midwives' roll. The licence shall remain in force till the thirty-first day of December following, and shall be revocable at any time by the local supervising authority in case the holder be proved to the satisfaction of the Central Midwives' Board to have infringed any of the regulations framed under this Act. The licence shall be issued on payment of a fee of 1s., it shall only be available in the county for which it is issued, and it shall be renewed annually on the first day of January."

He argued that this clause would inflict no hardship upon midwives, while it would be a safeguard against malpractice and crime.

Mr. **HEYWOOD JOHNSTONE** said that the object of the proposed clause was to identify and trace a woman who was practising midwifery in any part of the United Kingdom, but this was already provided for in the Bill. Clause 9 in the Bill said that any woman certified under the Act shall, before holding herself out as a practising midwife or commencing to practise as a midwife in any area, give notice in writing of her intention so to do to the local supervising authority and shall repeat the notice every year. It had seemed to those responsible for the Bill better to follow the precedent of the Infant Life Protection Act and to substitute for licensing a system of notification which they believed would carry out every one of the objects of this proposed new clause.

Sir **FRANCIS POWELL** said that while at one time he had been in favour of licensing he now favoured the scheme in the Bill, having come to the conclusion that licensing would create prejudice and difficulty.

Dr. **THOMPSON** argued in favour of licensing as likely to give greater control over the midwives.

Captain **NORTON** said that if this clause were added to the Bill the measure would be inoperative in a district like South London because a woman would have to take out half-a-dozen licences.

Mr. **ROBERT AMBROSE** saw no objection to a woman being required to take out a license for each of the areas within which she carried on her practice.

On a division the proposed clause was rejected by 128 votes against 59.

The House then proceeded to the consideration of the clauses in the Bill.

Clause 1 said that "from and after the first day of January, 1905, no woman shall be entitled to take or use the name or title of midwife (either alone or in combination with any other word or words), or any name, title, addition, or description implying that she is certified under this Act or is a person specially qualified to practice midwifery or is recognised by law as a midwife, unless she be certified under this Act."

Mr. **ROBERT AMBROSE** moved to insert after "shall" the words "habitually and for gain attend women in childbirth or shall." He explained that these words were in the Bill of 1900 and argued that they were necessary to prevent unqualified women from practising

Mr. T. P. **O'CONNOR** appealed to the Government to reconsider this matter. In his opinion the insertion of these words would strengthen the Bill. He had been asked by the British Medical Association and the General Practitioners' Association to support this amendment and he believed that the General Medical Council was also in favour of it. Though he might not be able to say that the entire medical profession stood behind the amendment he was entitled to say that it had the support of all the great representative medical bodies. The object of this measure was to diminish mortality and suffering which arose from bad midwifery and, in his opinion, it required amendment to achieve that object. The training of these women would be very much inferior to the training of registered medical practitioners who practised midwifery, but quite apart from the trained women the Sairey Gamps would be left absolutely free to go on with their operations. He felt sure that those members of the House who would vote with the promoters of the Bill would do so under the impression that the Bill was going to do away with the old, bad, dirty, and incompetent Sairey Gamp. That was the reason why so many Members were in favour of the Bill and he did not blame them. But he would point out that the Bill in its present form did nothing of the kind. There was not a provision in the Bill which would interfere with any woman who chose to practise midwifery. The Bill gave a right to take up certificates, but there was no penalty for those who went on practising without certificates. It was understood that the objection to the amendment came from the Home Office rather than the promoters of the Bill. Indeed, he understood that if they had to deal only with these gentlemen the amendment would be accepted. What was the objection? The objection was that this would make the practice of midwifery by uncertified women a penal offence. Why should it not be? If a woman chose to take upon herself all the risks involved in attending women in labour it was surely right that she should be called upon to give some proof of her fitness for the work. In his early days he had known many unqualified medical men. They were men of great practical experience and competence. But the unqualified medical assistant had under the operation of the Medical Acts disappeared ...

Mr **HEYWOOD JOHNSTONE**: Do I understand that the unqualified assistant would be subject to a penalty if he attended a case?

Mr. T. P **O'CONNOR**: I know this, that if a medical man employs an unqualified assistant he gets into trouble

Mr. **HEYWOOD JOHNSTONE**: That is another matter.

Mr. T. P. **O'CONNOR**: The medical man is liable.

Mr. **HEYWOOD JOHNSTONE**: Is the unregistered practitioner punished? That is the point

Mr. T. P. **O'CONNOR** said that the unqualified assistant had disappeared He could see nothing in the objection of the Home Secretary. If the law was not strong enough to keep the quack from practising, then the Law should be strengthened It was intolerable that so many lives should be lost or darkened by these practices and that the law should not be allowed to interfere If the law was defective in regard to the quack, that was no reason why in creating a new profession they should not make the law sufficiently strong. If the Home Secretary were to meet him upon this amendment his main objection to the Bill would be removed. He knew there were some difficulties but they were not insurmountable. Undoubtedly, a large number of these women had been in practice for years, and it might be regarded as a harsh thing that they should be at once deprived of their livelihood, but if the Home Secretary would accept the amendment in principle he would be quite willing so far as he was concerned to accord them a period of grace.

Mr. **RITCHIE** said he wished to remind the house of the object of this Bill. That object was a very proper one and a very simple one. At present, as the House knew there was nothing whatever to indicate to any person who wished the assistance of a midwife whether the woman was qualified or not. The authors of the Bill thought, and in his opinion rightly thought, that it would be very desirable that when a person required the assistance of a midwife the person should be in a position to know who had got and who had not got the qualification. Therefore there was set out in the Bill a means by which this knowledge could be obtained. If this amendment were carried the Bill could not proceed.

Several Members: Why not?

Mr. **RITCHIE** said that it could not proceed because it would be most unjust and most injurious. If carried this amendment would mean that no one would be allowed to practise at all for gain unless she was certified. Any poor woman in need of assistance would be unable to avail herself of any assistance of this kind except at the hands of a medical man.

Several Members: No, no.

Mr. **RITCHIE**: I beg pardon, that is so.

Several Members: Why?

Mr. **RITCHIE**: Because there would be no one in a position to obtain a certificate. I do not mean to say that the time might not arrive.

Mr. **ROBERT AMBROSE**: There is the word "habitually" in the amendment.

Mr. **RITCHIE** said that no woman would be of any value unless she had been in the habit of practising They could not call a person out of the street to practise. If this amendment were carried many women who had been in the habit of practising would be barred and there would be much suffering and hardships in consequence The hon. Member (Mr. O'Connor) spoke very strongly and with deep conviction as to the necessity of this amendment and it would probably surprise the House to learn that the hon. Member in the Grand Committee voted against it.

Mr T. P. **O'CONNOR** said that he was not ashamed to confess that he had changed his opinions on the subject.

Mr **RITCHIE** quite accepted this, but the House hearing him speak would scarcely have imagined that the hon. Member in the Grand Committee had voted against this amendment. The House was asked to reverse the opinion of the Committee in a matter vital to the Bill. He could not support the Bill if this amendment were put in and he did not believe the House would for one moment consent to a step which would at once deprive poor women of the assistance which they had been in the habit of receiving from women who though not certificated were in the habit of attending midwifery cases and doing good work. That was the reason why as Home Secretary he objected to this amendment.

Mr. T. P. **O'CONNOR** reminded the Home Secretary that it had been suggested that a period of grace should be given to women now in practice.

Mr. **RITCHIE** admitted that that was a considerable modification, but his own view was that it was very much better to pass a moderate Bill such as now they had before them, and then in course of time—he did not think that it need be any very prolonged time—they might be able to bring forward before the House with a chance of success something much more drastic in its provisions than anything in this Bill. He thought that they should be content to proceed by degrees, and the fact that everything that medical men desired was not in this Bill should not deter the House from taking this proposed step in the direction of reform

Sir **WALTER FOSTER** said that he supported the amendment. It was a matter of profound disappointment to him and to others who for many years had been working for the education of midwives that an amendment like this should not be accepted. The Home Secretary had said that this amendment would deprive people of a means of livelihood who had been in the habit of practising Nothing of the kind would occur because under the Bill every one of those women who was of good character and competent and suitable for the work would be able to obtain certification if she applied within two years of the commencement of the Act; and, again, no woman would be prevented in the terms of the Bill from giving such assistance to her fellow women as humanity demanded What was desired was to have some effective means of preventing ignorant and improper persons from adding to the number of puerperal deaths in the country. The Bill of 1900 contained this provision, and he thought that the Home Secretary should have the courage to accept it. It was notorious that hundreds of lives were sacrificed through the error of these incompetent persons It was contended that there were no precedents in the statutes for making it an offence for an unqualified person to practise and that if they enabled the poor to find out who were properly qualified that was all that was necessary for their protection. All the experience of registration was against that view. In the medical profession they had had 40 years of registration which enabled the public to find out who was on the Medical Register and who was not, and he would assert this—that not one person in 1,000,000 of the population of this country ever looked at the Medical Register or ever took any notice of it when he selected a medical attendant. When the Medical Act was passed it was fondly hoped that it would do away with unqualified practice, but, as a matter of fact, that practice flourished as much as ever and the Act had done nothing to stop it. At the present moment there were thousands of herbalists carrying on their practice in all the large towns. Bonesetters, too, flourished as of old, as well as people who used spiritual healing and things of that kind. The Medical Act drawn upon the same lines as it was proposed to draw this Bill had had no power to stop the practice of such unqualified practitioners or to protect the public against impostors. He did not wish that a similar mistake should be made in this very delicate and serious matter with which they were now dealing. This Bill created a new class of practitioners and did not touch in any way a class of incompetent women who were now engaged in practice. All that these women would be prevented from doing would be to call themselves midwives and these women rarely so called themselves.

Mr. Jessie Collings said that the practical effect of this amendment would be to prevent in country places lying-in women receiving the assistance to which they had been accustomed. They could not afford to pay for medical men and their habit was to call in a neighbour who not only attended the confinement, but looked after the other children and the general household affairs, receiving perhaps 7s. or 8s. a week for her services. It might be that there were Sairey Gamps among them, but many of them did their work well and were entitled to consideration.

Mr. Richards supported the amendment and suggested that special provision might be made for the class of persons referred to by Mr. Jesse Collings.

Mr. Heywood Johnstone admitted that there was something to be said for the amendment, but he said that there was no precedent for anything of this nature except the Apothecaries' Act. He appealed to the House to consider the existing state of things and the need for a remedy, while at the same time he expressed some sympathy with the idea of according to women at present engaged in practice a period of grace.

Mr. T. P. O'Connor asked for some assurance on this point.

Mr. Heywood Johnstone said that he was not entirely free in this matter, but he would do what he could to meet the wishes of the hon. Member.

Mr. T. P. O'Connor asked whether he might take it that the hon. Member would have the assistance of the Home Secretary.

Mr. Ritchie said he did not wish in the least degree to fetter the freedom of action of his hon. friend (Mr. Heywood Johnstone), but he would undertake to consider the question. He could go no farther than that.

Mr. Bousfield suggested that the period of grace should be extended to Jan. 1st, 1910.

Mr. Dillon supported that idea.

Mr. Heywood Johnstone said that he did not feel justified in putting the responsibility for this upon the Home Secretary, but he himself would undertake to consider the matter.

Sir Walter Foster asked the Home Secretary whether he would give the matter his favourable consideration.

Mr. Ritchie replied that he did not propose to oppose the amendment—at any rate at the present stage.

The House then agreed to the amendment with the extension of the period of grace to Jan. 1st, 1910.

Sub-section 6, saying that "no woman shall be entitled after the first day of January, 1905, to recover any fee or charge for attendance as a midwife unless she is certified under this Act," was struck out of the Bill.

In Clause 2 the special recognition was extended to the Coombe Lying-in Hospital and Guiness's Dispensary and the Rotunda Hospital for the Relief of Poor Lying-in Women of Dublin, and provision was made for the practice having lasted at least a year.

In Clause 3, dealing with the constitution and duties of the Central Midwives' Board, an amendment was inserted providing that one of the members of the board shall be a person appointed by the Royal British Nurses' Association who shall be a member of that body

One or two other amendments of a drafting nature were also introduced.

Mr. Griffith-Boscawen moved to extend the application of the Act to Scotland and Ireland. He did not know, he said, that there were fewer cases of preventable mortality in these countries than in England and he saw no reason why they should be excluded from this legislation.

Mr. T. P. O'Connor said that if a Bill of this kind for Ireland were introduced he should support it but he did not think that the present Bill could be extended to Ireland.

The Solicitor-General for Scotland (Mr. Scott Dickson) said that the Bill was drawn as an English Bill and many of its provisions could not apply to Scotland.

Dr. Farquharson hoped that on some future occasion a Bill for Scotland would be introduced.

Mr. Heywood Johnstone agreed that it would be difficult to apply the Bill either to Scotland or Ireland.

On a division the amendment was rejected by 237 votes against 23.

This completed the report stage and the Bill was ordered for third reading.

Broadbent.—On June 2nd, at Seymour-street, the wife of John F. H. Broadbent, M R C.S, M.R C P Lond., of a daughter.

Mackintosh—At Grahamston, Troon, N.B, on 5th inst., the wife of Hugh J. Mackintosh, M.B., C M, of a son.

MARRIAGES.

Escombe—Stephenson.—On the 4th inst., at St. James's Church, Grimsby, by the Rev. E Bulloch, Vicar, assisted by the Rev. H. F. Walker, William Escombe, M.R C S, L R C P. Lond, third surviving son of the late Rowland Escombe, Esq., of Blackheath, and 3, East India avenue, London, to Mildred Isabella, third daughter of G. S. Stephenson, Esq., M D., of the Manor House, Grimsby. (South African and New Zealand papers please copy.)

Griffiths—Davies.—At Mount Pleasant, Swansea, on June 4th, by the Rev. James Owen and the Rev. C Griffiths, Cornelius A. Griffiths, F R C S., Cardiff, and Lallie, youngest daughter of the late J. R Davies, of Swansea.

Hamilton—Darbishire—On June 4th, at the English Congregational Chapel at Penmaenmawr, by the Rev. David Walters of Headingley, Leeds, assisted by the Rev. S. C. Hart of Penmaenmawr, Graeme, younger son of Dr. Alexander Hamilton of Ashton-under-Lyne, to Mary Lilian, eldest daughter of C. H. Darbishire of Plas Mawr, Penmaenmawr.

Hearder—Hearder—On the 4th inst., at St. David's, Carmarthen, by the Right Rev. the Lord Bishop of Perth, W.A., assisted by the Rev. T. R Walters, vicar of the parish, and Prebendary C. G. Brown, Thomas Browne Hearder, M.B., C.M., Ilkley, Yorkshire, to Isabella Annie, third daughter of the late George Jonathan Hearder, M.D., Carmarthen At home July 7th to 11th.

DEATHS.

Armitage.—On June 2nd, at Wormit, Fife, Walter Stanley Armitage, F.R.C S. Edin.

Barnes.—On June 10th, at Dartmouth Park-road, Highgate, Clifford Henry Barnes, M B Camb, in his 30th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths

Notes, Short Comments, and Answers to Correspondents.

THE MEDICAL CURRICULUM AND THE GENERAL MEDICAL COUNCIL.

IN THE LANCET of May 10th we referred in a leading article to a report drawn up by Dr. Norman Moore, the representative on the General Medical Council of the Royal College of Physicians of London, of the proceedings at the special session of the Council held in February concerning the preliminary education of the medical student At this meeting a report of a committee was presented, which report in a recommendation stated that the qualifications of the two Royal Colleges of London, of the Universities of Oxford and of London, of the two Royal Colleges of Edinburgh, of the Faculty of Physicians and Surgeons of Glasgow, and of the Society of Apothecaries of London "do not secure that the persons holding them possess the requisite knowledge and skill for the efficient practice of their profession." The portion of the report containing this somewhat remarkable statement was by leave withdrawn. Seeing that if pushed to its logical end the recommendation would imply that most of the members of the General Medical Council did not possess "the requisite knowledge, &c.," we do not wonder at its withdrawal. A pseudonymous correspondent, however, writing to the *Lincolnshire Echo* of May 19th, takes our leading article and the matter upon which it was founded as material for an attack on the University of London alone, hinting that the recent alterations made in the matriculation examinations of that university are due to the statements made by ourselves. Such a misreading is foolish and absolutely unwarranted, as the writer of the letter in point will see if he takes the trouble to read our remarks again.

THE NEW YORK LIFE INSURANCE COMPANY AND SPINSTER PROPOSALS.

A CORRESPONDENT writes to us that he recently had occasion to examine a female candidate for insurance in the New York Life Insurance Company. Among the questions to be filled up as answered by the medical examiner as a result of his examination were certain questions relating to the matter of pregnancy. Through these he simply drew his pen, leaving them unanswered. On the form being returned to the company our correspondent received the following letter:—

> DEAR SIR,—
>
> *Re* Application Miss ——.
>
> In your report on the life of this party you omit to reply to the question, "Is she now pregnant?" We presume that being an unmarried woman you did not think it necessary to reply to the question, but we would point out that our Board have found it necessary to insist on a reply being given to this query in every case, in order to protect themselves against moral risk. We presume that you assured yourself on the point when examining party, and that you will be able to give us a definite answer without again seeing her. We shall be glad to hear from you in the matter at an early date.
>
> Yours truly,
> C. SETON LINDSAY, General Manager.
> H. —— L. H. Per R. E. H.

Now we quite see that an insurance company must protect itself and also it is an undoubted fact that unmarried women have been known to be pregnant. But we do not hesitate to say further that it is impossible for any medical man to assure himself that a normal woman is not pregnant even by the most thorough examination and to such a one no examiner would think of submitting an unmarried woman simply for a life insurance. More especially we note that the form to be filled up is headed, "This examination must be made in private, no agent or third person being present." This rule to our minds absolutely precludes an examination for pregnancy in an unmarried woman, nor do we believe for one moment that any director or official of the New York Life Insurance Company would permit his daughter or his sister to be examined in private for such a condition. Our correspondent asks how he should reply to the letter which we have quoted. We should advise him to reply that he had not assured himself on the point and that it would be impossible to do so, but that he had noted no definite signs of pregnancy. He might also communicate with the candidate and send her answer to the company.

A MODERN CATHOLICON IAMA.

A PAMPHLET has been widely distributed by post in which a medicinal preparation is highly extolled. It is apparently a compound but the formula is not given, the only information under this head being that the preparation "contains the Essential (anti-nervous) Active Principles of —— and Aromatics." Amongst other virtues the preparation "insures nerve tranquillity by inducing neural equilibrium." Anyone can at once see from this that "its use is necessary to normalize nerve tension in the treatment of fevers, colds, child birth, etc." Space being *ostensibly no object to* the pamphleteer it seems strange that the rest of the affections and diseases curable by his catholicon should be buried in an *etcetera*. The busy practitioner, for whom so many things are made easy

"I may remind you that this impurity of the waters supplied during the winter months is no new thing. I have reported on it year after year since 1873, and you may remember that you have addressed complaints to, and received similar answers from, the water companies many times before.

"I may also remind you that I have pointed out that for several years (with the exception of 1897) there have been more cases of enteric (typhoid) fever in the parish per month during November and December than during the preceding three months, and also that this disease has been unusually prevalent and fatal in London during the last three months. Now November, December, and January are not the months for the 'seasonal prevalence' of this disease, and, therefore, some other cause for the excess of it must be sought for, and it may be something more than a coincidence that in those very months London is supplied with water which, according to Sir Edward Frankland's report, contains 'an excess of organic matter.'" (Feb. 14th, 1899.)

In answer to this the following letter signed by Sir William Crookes for himself and Professor Dewar was sent to the vestry clerk by the directors of the Grand Junction Water Company :—

"Our attention has been drawn to a special report on the water-supply by Professor W. H. Corfield, medical officer of health to the Parish of St. George, Hanover-square, from which it appears he confirms the opinion of Mr. Cassal that the water delivered by the Grand Junction Company during December last was of inferior quality. This is diametrically opposed to the opinion we have arrived at from our extensive experience of the conditions of the water-supply from day to day.

"Dr. Corfield draws attention to the fact that both our report and that of Sir Edward Frankland on the character of the water supply to *the metropolis during December last* show that the majority of the Thames-derived supplies contained an amount of organic matter in excess of the average amount. This observation is simply an expression of the fact that all river-derived supplies have a period of maximum and minimum amount of organic matter during the course of the year. The maximum generally occurs in Thames water during the winter months and the minimum during the summer; and, as Sir Edward Frankland stated in his report for December, the over-charge of organic matter was 'almost entirely of vegetable origin.'

"The same remark applies to the amount of oxygen required to oxidise the organic matter. It is nothing unusual for river supplies to require three times as much oxygen during some period of the winter as compared with the summer supply. With regard, then, to the Thames supply during the month of December last, there was nothing exceptional in the oxygen absorption.

"Dr. Corfield, having pointed out these admitted facts, nevertheless puts an erroneous construction on what Sir Edward Frankland and ourselves intend to convey by our statement that the water before delivery had been efficiently filtered. Dr. Corfield seems to think that this is intended to express that the supply contained 'no notable quantity of suspended matters,' whereas our intention, and no doubt that of Sir Edward Frankland, was to convey that the water had not only been freed from matter in suspension, but had been bacteriologically purified to the extent of over 99 per cent. from its natural condition; thus removing the suspicion of the possibility of its conveying any water-borne disease.

"Dr. Corfield proceeds to point out that enteric fever has been more prevalent in the parish of St. George, Hanover-square, during November and December than during the three preceding months and that the same remark applies to London generally. From this occurrence, combined with the fact to which we have above referred, relating to the organic matter, he suggests that the coincidence may be attributed to the cyclical excess of organic matter which occurs during the winter months.

"All the facts are against any such hypothesis. Our recorded analyses of the Thames-derived waters since 1881, together with the Registrar-General's statistics of enteric fever, enable us to state that *there is no causal relation* between the two. Indeed, this must inevitably be the case, for it is common knowledge that if any such disease as enteric fever originates through a contaminated water-supply, it is not the *amount* of organic matter but its *nature* that is the dangerous factor and this must be the presence of the specific living germ characteristic of the disease.

"No one has alleged that Thames water which has undergone storage and filtration similar to that of the London supply contains any such pathogenic organisms. It is true that Dr. Corfield seems to entertain a different view of the origin of typhoid epidemics, for during the course of the Maidstone inquiry, when it was proved beyond all doubt that one of the sources of supply had been grossly contaminated with fæcal matter and had been distributed to Maidstone without proper and systematic, or indeed any, filtration, Dr. Corfield, while admitting there had been pollution, said 'it was some vegetable pollution that had got in.'

"There is no comparison between the conditions of the polluted spring water-supply which originated the Maidstone epidemic and any polluting conditions which can arise in the Thames valley, where strict supervision of all sources of contamination is so efficiently maintained—a supervision which we know has materially improved the condition of the raw river water over what it was 10 years ago.

"We say deliberately that after mature investigation we know of no example of a water-borne disease having originated from a river supply where proper precautions are taken for adequate storage and effective filtration, such as exist in the case of the London water-supply." (31st March 1899.)

This was referred to me by the committee of works, and I prepared the following answer to it, which was issued as a "Further Special Report on the Water-supply" :—

"In accordance with your instructions I have considered the report forwarded to you by the Grand Junction Waterworks Company, and signed by Sir William Crookes on behalf of himself and Professor Dewar, the company's analysts, and beg to report thereon as follows :—

"The report in question admits the fact that there is an excess of organic matter in the filtered river water supplied to London in winter, and explains it by the statement 'that all river-derived supplies have a period of minimum and maximum amount of organic matter during the course of the year. The maximum generally occurs in Thames water during the winter months and the minimum during the summer.' This is another way of stating what I have pointed out for many years past, that the water supplied by the Thames water companies during the winter frequently, and indeed usually, contains an excess of organic matter, due to the fact that the river water in winter is dirty from the washing of polluting matter from various sources into the river. To say that there is nothing exceptional in the occurrence of an excess of organic matter in the water in winter is merely to admit that the water in winter is generally polluted.

"The report next accuses me of putting an erroneous construction on what Sir Edward Frankland and the writers intend to convey by the statement that the water before delivery had been 'efficiently filtered,' in saying that this was intended to express that it contained 'no notable quantity of suspended matters,' whereas their intention 'was to convey that the water had not only been freed from the matter in suspension, but had been bacteriologically purified to the extent of over 99 per cent. from its natural condition.' This would seem to imply that bacteria are not suspended in the water, but as that cannot be intended I need only reply that I included them among the suspended matters, that my statement was strictly correct, and that apparently efficient filtration is not to be considered to include the removal of foul organic matter in solution in the water.

"The non-removal of such organic matter is, then, admitted by the company's analysts, and I may remind you that Sir Edward Frankland in his report for December, referring to the Thames companies, says that 'owing to heavy floods and insufficient storage the water sent out by all the companies, except the West Middlesex, contained an excess of organic matter which was, however, almost entirely of vegetable *origin,' but the writers of the report in question go on to* traverse my very temperate statement that 'it may be something more than a coincidence' that the exceptional prevalence of enteric fever in London during November, December, and January, which are not the months for the seasonal prevalence of this disease, occurs in the very months in which London is supplied with water which contains 'an excess of organic matter.' They say 'it is common knowledge that if any such disease as enteric fever originates through a contaminated water-supply it is not the *amount* of organic matter but its *nature* that is the dangerous factor, and this must be the presence of the specific living germ characteristic of the disease. No one has alleged that Thames water which has undergone storage and filtration similar to that of the London supply contains any such pathogenic organisms.'

"In answer to this I may, in the first place, point out that Sir Edward Frankland and others have over and over again found organisms in the filtered Thames water supplied to London, considerably in excess of the number taken as the standard—viz., 100 microbes per cubic centimetre.

"In a report recently issued by the Joint Public Health and Water Committees of the London County Council, I find that 'in the years 1896 and 1897 Sir Edward Frankland made 199 examinations of filtered water for the purpose of ascertaining the number of bacteria, and found that they varied from 16,000 per cubic centimetre down to nothing. The average, taking the whole of the 199 examinations, gave 232 per cubic centimetre, the standard admitted by Sir E. Frankland being that they should not exceed 100 per cubic centimetre. Out of the 199 days' examination by Sir E. Frankland there were 55 days in which the bacteria exceeded the standard, and for the whole 55 days they averaged 763 microbes per cubic centimetre; so that 28 per cent. of the results of Sir Edward Frankland's examination tend to show that the filters are not an effectual barrier against the passage of bacteria.'

"In the twenty-sixth annual report of the Local Government Board Sir E. Frankland states that 'in June, 1896, nearly the whole of the filter beds of all the companies became infected with bacteria.' Further on the same report states that 'the engineer of the Southwark and Vauxhall Water Company in the evidence recently given by him before the Royal Commission on London Water Supply admitted that in December, 1896, 16,000 bacteria per cubic centimetre were found in water that had passed one of their company's filters and that nothing was discovered to explain the fact.

"Drs. Parkes and Rideal have recently submitted a valuable joint report to the Chelsea Vestry on their examination of the water supplied by the Chelsea Waterworks Company from November, 1897, to November, 1898. In this report they clearly show that organisms of various kinds and in varying numbers passed through the filter-beds, some of these organisms being of the kind of which the bacillus coli communis, which is found in enormous numbers in sewage, is a type; and being found in 19 per cent. of the total number of specimens tested for them. Of this test they remark: 'The test, also, when it gives an affirmative result, not only tends to indicate the tainted sources of supply of the Thames, but also tends to show that the methods of sand filtration pursued by the company are ineffectual in eliminating from the filtered water microbes of which the common resting place is sewage and animal excrement.' The conclusions they arrived at are 'that even in a year exceptionally favourable to the purifying operations undertaken by the water companies, the element of danger necessarily attaching to the supply of a water taken from sources inevitably exposed to contamination is not by any means invariably eliminated by the methods of purification at present relied upon. A system of filtration which does not invariably keep out or destroy the common accompaniments of sewage and animal pollutions may, on the occasion of epidemic prevalences in communities on the river banks above the companies' intakes, also allow the passage of the infective disease organisms in numbers sufficient, as the case may be, to cause epidemics amongst the water consumers, or mere sporadic outbreaks, or isolated occurrences amongst the more susceptible of the population. We are, therefore, of opinion that considerations of public safety require that reliance should not be placed upon sand filtration as at present conducted, as the sole means of defence, when the water to be operated upon is derived from a tainted source. The question of the presence of "blood-heat" organisms in the water, their relations to season and to water temperature, and to the occurrence of diarrhœal complaints in the late summer, to which some reference has been made above, appear to be deserving of more prolonged and detailed investigation.'

"As to the fact that 'pathogenic organisms' have not been found in the water supplied by the Thames companies I need merely say that the bacillus *of enteric* fever has rarely, if ever, been found in any water-supply. It was not found, for instance, in any sample of water supplied nowadays, would surely like to know whether the catholicon would cure ringworm, for example, or a fractured patella. The inference is fair that it could but one would like to be sure. The extraordinary merits of the catholicon are vouched for by no fewer than 33 medical men, all residing in America. The diseases which these gentlemen were able to subdue by means of it are specified as follows in their testimonials, which, together with their names and addresses, are reproduced at length in the advertising pamphlet: extreme nervousness (2), irritable nervousness, nervous exhaustion from mental work, abortion, metritis, the drug habit, spasms, nerve irritation, neuralgia (2), ovarian trouble, painful menstruation, street accident, hard work in starting an uphill practice, mania, dyspepsia, chorea, urticaria, prurigo, insomnia, malarial fever, melancholia, old age, teething, ovarian hyperemia, neurasthenia (3), locomotor ataxia, neuritis, puerperal fever, nervousness, la grippe, St. Vitus's dance, intense nervousness, and finally, in the case of a "nervous pervert" In addition to the foregoing 26 more medical men, all residing in America, testify in general terms to the marvellous curative properties of the catholicon No wonder, therefore, that the exultant pamphleteer should exclaim in conclusion: "In teaspoonful doses three or four times a day —— adds laurels to the skill of the physician" He fails, however, to draw attention to yet another marvellous thing in connexion with his catholicon. It is "Prepared Exclusively for Physicians' Prescriptions" and at the same time is "kept in stock" by druggists for sale across the counter.

THE BIOLOGICAL THEORY OF CANCER.

To the Editors of THE LANCET

SIRS,—As there seem to be the beginnings of great efforts in Europe at the present time to fathom the cause of cancer may I be permitted to lay before the profession the following short preliminary note upon a theory of the origin of cancer which I hope to elaborate at a later date? According to this theory the natural history and histology of epithelioma and carcinoma are more reasonably explained, in my opinion, than upon any other hypothesis. Immediately after the fertilisation of the ovum its protoplasm shows spontaneous movements, then growth and division, each smallest division being also endowed with the foregoing three powers, viz.: (1) movement; (2) growth; and (3) division Each cell of the embryo—the infant, the adolescent, the adult, and the aged—during the life of the individual and of itself (the cell) possesses these three powers, increasing in quantity during infancy and adolescence, more or less constant during adult life, decreasing in quantity during old age, solely, as far as is known at present, by virtue of the impregnation of the female ovum by the male sperm cell. The animal body, therefore, during life possesses an influence, vital or biotrophic (Gowers), which permeates every cell of every tissue and keeps going, so to speak, the three vital properties before mentioned of movement, growth, and division It is quite reasonable to expect that if this influence, whether increasing, stationary, or decreasing, be in any way cut off from one tissue, the neighbouring tissues will benefit to a corresponding extent and will exhibit the three vital properties in an exaggerated degree. We see this in compensatory hypertrophy, where one of two organs has been removed or is diseased and also in the tendency to abnormal growth of hair in dementia. We are bound, I think, to apply this principle when dealing with the minute structure of organs and then we shall perceive that interference with the properly regulated supply of biotrophic influence to the skin and glands, which is most likely to occur during the period of decrease, might easily produce in the one case epithelioma and in the other carcinoma by the cutting off of this influence to the basement membrane in each case, thereby allowing a fuller supply to the tissues on each side of it, resulting in more marked growth and cell division The basement membrane would disappear and allow the epithelium and tissues of the true skin to commingle in their exaggerated growth; so too, in carcinoma. We see in the warts of childhood local overflows of biotrophic influence, they are not epitheliomata because the basement membrane is intact and if destroyed can re-form. Adenomata are local overflows of this influence to the glands, they are not carcinomata on account of the existence of the membrana propria. This principle can, I think, be shown to be very extensive in its ramifications, but I will say no more on the subject at present, merely hoping that in the future more attention will be paid by those who are so earnestly working for the benefit of the human race, to the study of the nature of life, and the laws of growth.

I am, Sirs, yours faithfully,

WALTER H. HAW, B.A., M.R.C.S. Eng., L.S.A.

Knysna, Cape Colony, May 16th, 1902.

A PLEA FOR THE FINAL YEAR STUDENT

To the Editors of THE LANCET

SIRS,—May I be allowed to reply to Mr. R. H. D Pope's letter on the above, published in THE LANCET of May 31st, p. 1579, as I think he has failed to appreciate properly the value of the training which I imagine he has received? Surely he cannot seriously maintain that all that is worth knowing about pharmacy can be gathered in a couple of hours' study! Anyone who attempts to prescribe with intelligence must be aware how difficult it is to combine neatly and effectually even those few drugs which are most commonly employed, and it seems somewhat humbling for a medical man to be dependent on the word of a manufacturing chemist with regard to what is the proper combination to be employed in any particular case. Mr Pope objects to the student being worried over such subjects as biology and pathology because he does not think they help the "busy practitioner" in the treatment of his cases; would it not be as reasonable to refuse to teach a child the A B C because when he becomes a busy reader he will not have the time to spell through each word when he is skimming through a book? Again, he asks, what has bacteriology done to lessen the severity and shorten the duration of disease? Has Mr Pope ever heard of the antitoxin treatment of diphtheria? or of the importance of an examination of the sputum for the bacillus of tuberculosis in the diagnosis of early phthisis? I think not I gather that Mr Pope finds the use of antiseptics too troublesome for employment in his practice and that his confidence in them is decreasing.

I am, Sirs, yours faithfully,

June 2nd, 1902. N P. STALLARD, M.B. Lond.

THE ROYAL ASYLUM OF ST ANNE'S SOCIETY, REDHILL, SURREY.

MRS. EARLE, the daughter of a late deputy inspector-general of hospitals in India, requests us to call the attention of those of our readers who have interest in the above asylum to an appeal for votes on behalf of her daughter, Joyce V. D Earle, aged 10 years, "whose father had formerly a good medical practice ... but through reverses and misfortunes his health has broken down and he is quite unable to support his wife and three youngest children" Mrs. Earle states that her husband has had serious illnesses but that he is now better and trying to get an appointment. "Our means are quite exhausted," she continues; "this is the youngest of our family of 12, most of whom are now working for themselves, but three are still of school age and it would be the greatest boon if one could be provided for till she is 15."

RETREATS FOR THE SECRET CURE OF ALCOHOLISM

To the Editors of THE LANCET.

SIRS,—With your permission I beg for an expression of opinion from my *confrères* on the following points: (1) What is the subsequent history of cases who leave these institutions (alleged to be) cured? (2) how long should such cases subsequently remain absolute teetotalers before it could be safely inferred that the craving was dead? and (3) should a medical man recommend (or refuse to recommend) such retreats in cases where all his skill and all the patient's will power had failed to wean him from alcoholism? I notice that neither the *British Medical Temperance Journal* nor THE LANCET is enamoured of such means of effecting (?) a cure especially from the standpoint of prognosis. I know a gentleman who returned from a retreat presumably cured and now—he is three months home—he cannot stand even the alcoholic breath of anyone conversing with him without its almost making him vomit. Is this gentleman likely to continue with such a fortunately weak stomach or may the effects of the cure (?) by degrees pass off, leaving the old thirst behind?

I am, Sirs, yours faithfully,

QUÆRIST.

June 7th, 1902.

PROPOSED MEMORIAL TO THE LATE SURGEON-GENERAL W. NASH, A.M.S.

THE following additional subscriptions to the fund have been received:—

	£	s	d
Lieutenant-Colonel M. D O'Connell, R.A.M.C.	1	1	0
Lieutenant-Colonel R. P Hetherington, R.A.M.C.	0	10	0
Major J W. Bullen, R.A.M.C.	0	10	0
Brigade Surgeon Lieutenant Colonel A. A. Macrobin, A.M.S ...	1	0	0
Deputy Inspector-General G Saunders.	1	1	0
Lieutenant Colonel R. T Beamish, R.A.M.C	0	10	0
Colonel T Ligertwood	1	1	0
Brigade Surgeon S. H. Dickerson	0	10	6
Surgeon Major General C H. Giraud, A.M.S	1	1	0

A PLACE OF RESIDENCE.

To the Editors of THE LANCET.

SIRS,—Can any of your many readers kindly give me any suggestions as to the best place of residence for a man, aged 60 years, who is retiring from business, to take his abode in? He suffers slightly from rheumatism and eczema and has been living in the North-East of England; he now wants a warm yet "bracing" locality, not too hilly and where the water is "soft."

I am, Sirs, yours faithfully,

P. P

THE "Y" FUND

SURGEON-GENERAL H S. MUIR begs thankfully to acknowledge additional donations towards the above Fund from Professor J. Chiene, Professor T R Fraser, Professor A R. Simpson, Professor J. Wyllie, Dr J Halliday Croom, Dr P Heron Watson, Dr C. H. Underhill, Dr. Ronaldson, Dr J Crawford Renton, Dr Hunter, Dr. D. Argyll Robertson, Dr R. Milne Murray, Dr. R. J. Blair Cunynghame, Dr. J. Dunsmure, Dr Joseph Bell, Mr. Barclay; Brigade-Surgeon-Lieutenant-Colonel J Arnott, I.M.S. (retired) (the foregoing kindly collected by Mrs. Argyll Robertson); Major and Mrs. Hickman Morgan; Captain and Mrs. W. L. Beyts, Mr. C. Vincent Catterill; Brigade-Surgeon Lieutenant-Colonel G. R. Harrison, and the following officers of the Royal Army Medical Corps: Lieutenant-

Colonels W. Allan May, J. L. Peyton, R. D. Donaldson, and R. C. Gunning; Majors R. H. Hall, J. S. Edye, E. C. Freeman, and A T. I. Lilly, Captains H. N. Dunn, P. Evans, and L. Addams Williams; and Lieutenants L. N. Lloyd, H. M. Nicholls, and A. C. Duffey. The fund now amounts to £263. It may be explained that this is in response to an appeal made privately to members of the profession for benevolent aid in a distressing case which has been described in a letter sent to a limited number of medical men (who would help the cause by kindly "handing on" to *confrères*). Should any reader of THE LANCET desire further particulars with a view to expressing *practical sympathy*, a copy of the letter will be forwarded on application to Surgeon-General Muir, 26, Kensington-gardens terrace, Hyde Park, London, W.

FOREIGN MEDICAL LITERATURE.

A. C. C. asks · "1. Is there any subscription library from which German and French medical journals could be hired? 2. Where can one obtain a price list of the more ordinary and usually quoted German and French journals and the address of the publishers? One so often wants a single number, say, of Virchow's *Archiv*, *Centralblatt für Bakteriologie und Parasitologie*, &c."—1. We do not know of any such library. 2. Messrs. Williams and Norgate, Booksellers and Publishers, Henrietta-street, Covent-garden, London, have a "Deutscher Journal-Katalog für 1902" (price 2*s.*), which gives this information in full for all German periodicals arranged in 41 sections. Medical periodicals are described under Section 5 (Heilwissenschaft). They have also a somewhat similar but less comprehensive catalogue for French periodicals. With regard to Virchow's *Archiv*, which our correspondent specially mentions, we understand that the publisher does not sell single copies. Our correspondent is also reminded of the letter published in THE LANCET of May 17th, p. 1439, in which Dr. Eugen Cohn of Berlin gives the names of the leading German medical weekly periodicals.

THE LAW FUND.

TRUSTEES: THE PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON, THE PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND, AND THE MASTER OF THE SOCIETY OF APOTHECARIES OF LONDON.

"THE PEOPLE'S CHEMIST."

A COPY of the *Kent Herald*, dated June 4th, has been sent to us and certain paragraphs in an advertisement column headed "Medical" are marked for our attention. The character of the advertisements is such that their publication does not redound to the credit of the paper in which they appear, but the editor of the *Kent Herald* is not the only editor who advertises pills which will cure discharges from the urinary organs. All these so-called medical advertisements emanate from the Medical Hall of Canterbury where there apparently resides one Lander, the People's Chemist. This person says that he has a sure cure for influenza, a specific for tic doloureux, a most effectual remedy for coughs, colds, &c., and every modern appliance for sight-testing. He also sells penny royal and steel pills for females, and, as we have already said, pills for venereal discharges. If the *Kent Herald* could dispense with the patronage of Lander a regard for decency would be manifested and we are certain that no loss to the public would accrue

THE INJECTION OF COCAINE AND THE MORPHIA HABIT.

To the Editors of THE LANCET.

SIRS,—In reply to "F. G. B ," I would strongly advise the greatest caution in the use of cocaine for the cure of the morphia habit. It is better to give no substitute until the morphia has been suppressed entirely by the skin and that which is administered in its place by the mouth or rectum has been reduced to the least possible quantity—half a grain, for instance. If cocaine is given early in the weaning there is a great risk of the patient becoming addicted to it also, and for this reason he should never be allowed to know that he is taking cocaine. Given with these restrictions it is sometimes most useful but in some cases it cannot be tolerated, producing symptoms of distress that can only be relieved by return to morphia. It is safer, on the whole, to use the liquid extract of coca which when properly made is almost as efficacious without being dangerous Most of the fluid extracts of coca do not possess the full therapeutic activity of the plant. It would encroach too much on your space to go properly into this question but for the information of those who may be interested in the subject I will say that it is now recognised that preparations of coca from imported leaves cannot be relied upon. There is a something in the best fresh leaves which is lost in transmission to Europe. Messrs. Parke, Davis, and Co., however, make a "standardised" extract which is prepared from the fresh leaves as soon as they are gathered, which I would strongly recommend in the treatment both of the morphia habit and alcoholism.—I am, Sirs, yours faithfully,

Avenue Marceau, Paris. OSCAR JENNINGS, M D. Paris.

To the Editors of THE LANCET.

SIRS,—May I be allowed, in answer to your correspondent "F. G. B." to warn him against attempting to cure the morphia habit by the addition or substitution of cocaine? The injection of cocaine does not in the least degree assist in the cure, but on the contrary acts as a dangerous complication. Having had considerable experience of the treatment of morphia *habitués*, I shall be pleased, if "F. G. B." will communicate with me, to advise him how best to deal with his case. I inclose my card. I am, Sirs, yours faithfully,

J. H. C.

THE CENTURY TANDEM.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of May 10th, p. 1326, you review a book on motoring published in the Badminton Series, and in the article you allude to certain experiences of your own of a Century Tandem. I was on the point of ordering one of those machines but I have not been able to glean any information as to their general behaviour, and you would do me a considerable favour by giving me your opinion on the following matters:—

1. Is there much noise or more than usual in a small voiturette?
2. Much vibration, especially with the solid tyres?
3. Ample brake power, so that machine can be pulled up on steep descent? (This is a most important point for Northumbrian country.)
4. Given a fair amount of care and attention is it reliable and easy of management?

Thanking you in anticipation of reply,

I am, Sirs, yours faithfully,
H. W. CROSS, M.B. Durh.

Rye-hill, Newcastle-on-Tyne, June 6th, 1902.

*** The experiences were those of our reviewer, who replies to our correspondent's questions as follows.—ED. L.

1. It certainly is somewhat noisy; more noise is caused if the petrol is not fresh.
2. I am not aware that it has been built with solid tyres. Hard-pumped pneumatics give a good deal of jolting on rough roads.
3. The brake-power is ample.
4. It is more simple than most; but your correspondent should get a 1902 pattern. The chains on the older ones are too light and at a recent hill-climbing competition the second speed chain broke when going down hill.

The Treatment of Stammering.—"Koax-Koax," who recently appealed to our readers for information with regard to this subject, wishes to thank the many correspondents who so courteously responded to his request.

◆

Bengal Cavalry.—Much depends upon the kind of limekiln employed and upon the quality of the fuel. With a good tall shaft there is no reason why lime-burning should not be conducted without nuisance or injury to health either to animal or vegetable life. Lime burned in closed kilns, the vapours being carried into the upper part of the atmosphere, should create no offence. On the other hand, defective limekilns, especially those with no draft arrangement, are likely to be a distinct source of nuisance and may cause injury to health. Sulphurous fumes from the coal or coke would, of course, have injurious effects on vegetation. With old-fashioned limekilns it is desirable that dwelling-houses should be situated at least 200 yards away. Our correspondent will find some interesting information on effluvium nuisances in the report of Dr. Ballard contained in the annual report of the Local Government Board, 1876.

Belgium —All information can be obtained concerning the M D. Bruxelles from Dr. W. Reeve, 38, Manchester-street, W.

Health seeker must produce his diplomas to one of the three boards of examiners in California.

ERRATUM —In Professor Tansini's paper on Improvements in the Operation for the Radical Cure of Inguinal Hernia, published in THE LANCET of May 24th, 1902, p. 1463, two of the illustrations have been accidentally transposed. The instrument there marked Fig. 1 is a retractor and the instrument marked *Fig. 2 is a hook* for the spermatic cord.

During the week marked copies of the following newspapers have been received:—*Kent Herald, Western Morning News, La Caducée, Herts Advertiser, Times of India, Aberdeen Free Press, Blackburn Gazette, Bournemouth Guardian, Lancashire Post, Plymouth Morning News, Western Mercury, Yorkshire Post, Pioneer Mail, Citizen, Architect, Builder, Devon and Exeter Express, Burnley Express, Manchester Dispatch, Glasgow Citizen, Scotsman, Ipswich Times, Dublin Evening Telegraph, Southampton Echo, Belfast News, Birmingham Daily Mail, Lancaster Guardian, Bradford Observer, Sheffield Daily Telegraph, Municipal Reformer, Echo, Daily Mail, Daily Express, Yorkshire Post, Standard, Bristol Mercury, Windsor and Eton Express.*

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (16th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.) West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.).

TUESDAY (17th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Royal Ear (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.).

WEDNESDAY (18th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.).

THURSDAY (19th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

FRIDAY (20th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square, (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.).

SATURDAY (21st).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

TUESDAY (17th).—PATHOLOGICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8.30 P.M. Card Specimens:—Mr. Waring: (1) Congenital Lymphangioma of the Face; (2) Congenital Tumour of the Superior Maxilla. Papers:—Dr. Phear: Bone-marrow in a Case of Suppuration of the Knee-joint with Secondary Hæmorrhage.—Mr. H. J. Waring: Neuro-lipomata of the Median Nerve.—Dr. Fawcett: Chyle Cyst of the Mesentery.—Mr. H. J. Paterson: Dermoid Cyst of the Inguinal Canal.—Dr. C. Riviere: The Meningococcus in a Case of Cerebral Tumour simulating Posterior Basal Meningitis.—Mr. Shattock: Tuberculosis in a Python.

ROYAL STATISTICAL SOCIETY (9, Adelphi-terrace, Strand, W.C.)—5 P.M. Paper:—Mr. T. A. Welton: *A Study of some Portions of the Census of 1901.*

WEDNESDAY (18th).—ROYAL METEOROLOGICAL SOCIETY (Society's Rooms, 70, Victoria-street, S.W.).—4.30 P.M. Papers:—Mr. F. C. Bayard: English Climatology, 1891-1900.—Mr. W. L. Dallas: Earth Temperatures recorded in Upper India.

FRIDAY (20th).—SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (Pendlebury Children's Hospital, Manchester).—4 P.M. Papers:—Dr. A. E. Sansom: Some Remarks on Heart Disease in Children.—Mr. W. P. Montgomery: On Tendon Grafting, with Cases.—Dr. H. Ashby and Dr. G. Carpenter: On Splenic Enlargements, with some Observations on the Blood.—Dr. E. Cautley: Atresia of the Conus Pulmonalis, with Patent Septum Ventriculorum.—Mr. C. M. Gwynne (Sheffield): The Surgical Treatment of a Case of Infantile Paralysis of the Lower Extremity.—Mr. S. Stephenson: Fleeting Amaurosis in Children presenting Symptoms of Meningitis.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (16th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. A. Whitfield: Clinique. (Skin.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Edwards: Urethral Stricture.

TUESDAY (17th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. C. O. Hawthorne: Clinique. (Medical.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. S. Taylor: Heart Murmurs, their Significance and Treatment.

POST-GRADUATE CLINICAL DEMONSTRATION (Westminster Hospital).—4.30 P.M. Dr. D. Robinson: Menorrhagia, its Causes and Treatment.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury).—3.30 P.M. Mr. Horsley: Surgery of the Nervous System.

WEDNESDAY (18th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. E. W. *Roughton: Clinique.* (Surgical.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. McAdam Eccles: Surgical Anatomy.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. Wethered: The Treatment of *Pulmonary* Tuberculosis.

THURSDAY (19th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.)—4 P.M. Mr. Hutchinson: Clinique. (Surgical.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr Baldwin: Treatment of Injuries.

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Mr Steward: Treatment of Tubercular Disease of Joints.

CHARING CROSS HOSPITAL.—4 P.M. Mr. Waterhouse: Demonstration of Surgical Cases. (Post-Graduate Course.)

FRIDAY (20th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. W. Dodd: Clinique. (Eye.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Reece: Disinfection.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial *staff. It is urgently necessary* that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only. AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM				TO THE COLONIES AND ABROAD			
One Year	£1	12	6	One Year	£1	14	8
Six Months..	0	16	3	Six Months...	0	17	4

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

An Address

ON

THE RELATION OF BIOLOGY TO MEDICINE.

Delivered before the University College Medical Society on May 21st, 1902,

BY J. ROSE BRADFORD, M.D., D.Sc.,
F.R.C.P. LOND., F.R.S.,
PROFESSOR OF CLINICAL MEDICINE IN UNIVERSITY COLLEGE, LONDON; PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL, ETC.

MR. CHAIRMAN AND GENTLEMEN,—Before dealing with the subject which I propose to bring before you this evening I want to make a few general remarks about the great variety of subjects that the study of medicine gives us the opportunity of following. Every year the scope of these is widening, so diverse are the branches of knowledge with which medicine is related. There are many matters in medicine which bring it into close relationship with literary pursuits and more particularly perhaps with the writings and sayings of the ancient physicians and surgeons, and medicine in more modern days is getting more and more closely associated with a number of economic questions. A very recent development of this kind is afforded by the economic questions which are related to the establishment of sanatoriums, with reference more especially to the health of the working classes. Although all these questions are of interest and some are of very great and pressing importance the relation of medicine to scientific studies, to pure science, is becoming daily of far greater and increasing importance. It is the custom at the present day to look upon medicine still as an art—and no doubt it is in many respects an art, especially, perhaps, as regards the difficulty which the exponents of medicine have in transmitting their knowledge and acquirements to others, in which certainly medicine is more akin to an art than a science; yet I cannot help contrasting the position of medicine as a science now with what it was comparatively a very few years ago when I last spoke before this society. I cannot help contrasting it because of the very great progress that has been made in medicine. This progress when compared with that of its sister branch of knowledge—surgery—is often considered to be rather slow. Since I last spoke in this room, some 13 or 14 years ago, without wearying you with a mass of detail, I may take as illustrations of this progress three diseases which occur to me. At that time one's knowledge of these, certainly as regards diagnosis, was largely empirical, although with reference to one of them there was a certain amount of accurate scientific knowledge. The three diseases that I would allude to in reference to this particular point are tubercle, typhoid fever, and malaria. In all these diseases some 13 or 14 years ago diagnosis could not be said to be by any means accurate and was largely based on empirical knowledge, vague knowledge, and certainly not on accurate scientific results. At the present time no physician, if in doubt as to the presence of tubercle, whether of the chest or of other parts of the body, would rely on the ordinary methods of investigation that were then in vogue. He would call in the aid of an expert if he was not capable of doing the work himself; he would use the knowledge which had been obtained by purely scientific methods. When I was a student one had long descriptions of the differential diagnosis, for instance, of such a disease as typhoid fever from meningitis; there was a number of symptoms to which attention was drawn, and to the value of these in differential diagnosis great names were quoted. Now questions of that kind are often settled either by an examination of the urine or by an examination of the blood. The same remark applies to such a disease as malaria. I only mention these diseases by the way, as showing that even in medicine very striking results have been obtained by purely scientific methods of inquiry. I would further allude to one other method which at the present time is only at the threshold of its usefulness, at any rate in medicine, and that is the use of such a means of investigation as the Röntgen rays afford in the diagnosis of obscure diseases of the chest. When one thinks of the difference between 10 years ago and the present day in matters such as these one must admit the paramount importance of pure scientific knowledge for the adequate study of such a thing as medicine. A scientific training in medicine is essential from many points of view, and perhaps most of all to my mind from the fact that it is the only training that will give the physician or surgeon what may be called a proper habit of mind, and this quite apart from the use of a scientific training for its direct practical application. With these very scanty preliminary remarks I will pass on to the consideration of the subject-matter that I propose to bring before you.

Biology in relation to medicine may be considered from at least three points of view. It may be considered from the standpoint of a science of educational value and not simply from the point of view of its direct practical value in the study of disease but rather for the training that it affords to the human mind. It may, secondly, be considered in relation to practice, the immediate questions that present themselves to every practitioner in medicine; and it may be also considered from the point of view of the influence which it exerts, has exerted, and will exert still more in the future probably, on the progress of research in medicine. Although the second of these three is the one with which we are most often in actual contact the first and third are probably of more importance and it is a little difficult to say which of these two is the more important. In the training of the future medical practitioner it seems to me that it is most important that he should learn to pay due attention, but not an undue attention, to authority; and that he certainly should not accept statements simply because they are told him. He should verify these things for himself, and biology is certainly a science which enables that to be done by the student with very great facility. Further, if a man is to be a successful practitioner of his art he must be capable of observing with accuracy, and the different subjects that a medical student studies afford also different degrees of facility for attaining that object. Certainly the branches of biology, botany, and zoology, to my mind, are very valuable from this point of view; and I would like to say here that botany and zoology are no doubt from the point of view of training of very equal value, and further that it is not so very generally recognised nowadays as formerly that the old naturalist field work is a very excellent training from the point of view of producing accuracy of observation and accuracy of statement. Some of the most important and interesting discoveries in biological science have, even in recent times, been made by that branch of zoology which may be classified as the naturalist branch. An illustration of this in recent times is seen in Poulton, not to mention that great discoverers such as Darwin would come into this class. From the point of view of training biology offers special advantages to the medical practitioner and to the medical student because it enables him first of all to get, I think, a better idea of the complexity of living structures than he does by observation of the more purely technical branches which are more immediately related to the practice of his art.

I do not mean to say a word in disparagement of physiology, anatomy, or pathology, but when these things are studied from the exclusively human point of view it is rather doubtful, I think, whether the student gets such a good idea of the very great complexity of living matter and of living phenomena as he does if he studies the simpler forms of life. To the practitioner both of medicine and of surgery I would say that to my mind it is most essential for him—and I am afraid you may think I am going in for a great many platitudes—to have a thorough and ever-present conception before him of the extreme complexity of the phenomena with which he has to deal. Many of our mistakes and of the mistakes of others are dependent on not recognising this and thinking that things are much simpler than they really are. As regards the complexity of living matter an adequate study in the biological laboratory of the simpler forms of life—e.g., of an amœba or of the plasmodia formed by such organisms as the mycetozoa (which are easily observed by anybody and everybody and where many of the greatest problems connected with protoplasm can be observed with great simplicity and ease), gives a much better idea of the complexity of living matter than, say, the examination of a white blood corpuscle. A man gets a better general idea of protoplasmic activity from the study of the lower protozoa than from looking at a drop of human blood and studying the white corpuscles. I would therefore put in the forefront that one of the most striking uses of biology is that it affords an opportunity of examining and gaining an insight into the complexity of living matter. Not only does it do this but in the case of pathology, anatomy, and physiology—to take the three sciences which lie at the root of medicine—a study of biology in the broad sense of zoology and botany, but especially of zoology, enables one to obtain a very much wider grasp of the facts which are taught in these three sciences.

If you take such a science as anatomy—I will not weary you with many instances, but let us consider a few instances and first of all the case of the pineal body. Surely, the study of comparative anatomy, without necessarily going into it at any great length, affords the student an opportunity of getting a very much more intelligent appreciation of the pineal body than the mere study of it from the point of view of human anatomy. I do not mean that it is of great importance to know much about the pineal body from the practical point of view but I am only quoting this as an illustration of the mental culture and wider train of thought which it is desirable for you as medical men to have and the pineal body and its relation to a primitive eye afford a striking illustration of this fact. Another, perhaps not quite so striking an instance, is the case of the thyroid. Many of the problems of the thyroid, or at any rate some of them, receive a good deal of light from one's knowledge of the comparative anatomy of the thyroid body. Another very striking case is that of the suprarenal where not only has the study of the comparative anatomy of the suprarenal, especially in fish, thrown light on the anatomy of the organ and to a certain extent on its morphology but it has in a very striking manner confirmed some of the physiological doctrines which are held in reference to this body. One might go on to many others and I might mention the cerebral convolutions and the vena azygos and the whole, for instance, of Gaskell's work, whether one accepts it in its entirety or not. At any rate the study of these things gives one a very much wider grasp and very much more insight into the study of human anatomy and from that point of view is very desirable. Another one which I will not pass over is the question of the spinal segments and such elementary facts as that the legs are not posterior to the trunk. The morphology of the limbs is difficult to explain and to teach from the human point of view but is very readily taught and receives adequate illustration when it is looked at from the comparative point of view. I think that I have adduced enough instances to show that the study of comparative anatomy is of great use, even when not followed to any great extent, from the point of view of giving a wider grasp to one's knowledge of the facts of human anatomy.

Passing to physiology the same thing occurs and one might adduce a number of striking instances, but I will only take one or at the most two. Take such a thing as the function of respiration and look at it from the point of view of the human organism. You will necessarily come to the conclusion that lungs are necessary, that muscles are necessary, that blood corpuscles are necessary, that hæmoglobin is necessary, and that therefore iron is necessary. If you look at this function from the point of view of biology or of comparative anatomy you will be able to find illustrations in the animal kingdom in which each one of these several structures that I have mentioned may be absent. There are large groups of organisms without lungs but having branchiæ; there are organisms with lungs but with no diaphragm or with an incomplete diaphragm; there are animals which breathe with their skin; there are animals which have hæmoglobin dissolved in the blood plasm instead of in the corpuscles; and there are animals that have no hæmoglobin, as for instance, in the crustacea where the iron containing hæmoglobin is often replaced by a copper compound. Facts such as these which, as I say, can be acquired without any very great labour and which are of no direct practical utility, are at the same time of immense importance to a properly educated medical man from the point of view of enlarging his conception of physiological processes in general. There are similar illustrations to that adduced as regards respiration to be adduced as regards circulation, but I will not take up your time by going into that and I will not detain you with the very large question which is of very great interest to the physiologist and to the zoologist as to whether many of the micro-organisms in the alimentary canal are not really instances of complicated symbiosis, of which one has so many illustrations both in the vegetable and animal kingdom. It is a vexed question and one which this is not the place to enter into. I simply mention it as an illustration of the wider grasp afforded by an intelligent study of biology.

Coming to the question of pathology we learn that the debt of medicine to biology is very great. In the first place we have to remember that we practically owe our fundamental conception of cellular pathology, as most of you may know, to the botanist. It was knowledge acquired in the first place by the botanist and then transferred from the vegetable to the animal kingdom and then ultimately to morbid products. I think one is justified in saying that at any rate the conception of this matter we owe very largely to the botanist. There is another debt which pathology owes to biology and that is with reference to the doctrine of phagocytosis, whether we hold the extreme views of Metchnikoff on the subject or not. Without going into questions of priority as to who was the first person to observe phagocytosis in the case of white blood corpuscles in the mammalian organism there can be, I think, no question that the great importance of phagocytes, the fundamental conception of the way in which these cells devour invading bodies, that this fundamental conception in many of its details we owe to Metchnikoff. We must remember that he worked out the facts of phagocytosis in relation to man in a progressive series of animals beginning with the lower invertebrates, passing to the higher invertebrates in the form of the crustacean—a large amount of his work was carried out on the crustacea, on Daphnia, and from these he passed to other and higher forms. He made observations on animals that had no circulatory system at all but had these amœboid cells; then on those with a vascular system containing but few corpuscles in the circulating fluid; until finally in the higher forms he investigated animals in which the circulatory system was well developed. One of the great differences between the work of Metchnikoff and that of Cohnheim rests in the fact that the one worked on the higher forms of life where the phenomena were necessarily very complicated owing to the development of the vascular system and that the other was enabled to separate the part played by the phagocytes on the one hand and the blood-vessels on the other by working in a biological manner—that is, by working on organisms proceeding from the lowest to the highest. Metchnikoff was, of course, led to the study of phagocytosis in inflammation to a great extent from his own work and the work of others of a purely biological character—namely, the transformation of insects, the metamorphosis of insects, and the disappearance of the tissues of pupæ. It was by studies of this kind that he was led to his well-known views on inflammation. Whether the doctrine of phagocytosis is to explain all or many of the facts of immunity or whether it is not, there can be no question of the fundamental importance of the doctrine, and there can equally be no question of the fact that it is a doctrine which we owe very largely to biology. Another doctrine, another series of facts in pathology which we also owe to the biologists, is the phenomenon of chemiotaxis which is very closely allied to phagocytosis. Chemiotaxis is a subject of the greatest importance to the pathologist and of fundamental value. Chemiotaxis was first observed by De Bary and other botanists in their studies on the plasmodium of the mycetozoa—a group of the protozoa where by the confluence of large numbers of amœboid forms masses of living semi-fluid protoplasm of large size are very readily formed. De Bary and others were enabled owing to the facility with which this mass of protoplasm could be examined to observe the fundamental phenomena of chemiotaxis and the way in which this mass could be made to move in one direction by putting near it a material which it liked and it could be made to move backwards by putting close to it material which it did not care about. You can easily carry out these observations for yourselves on one of the common forms of mycetozoa called *Badhamia utricularis*. The mycetozoa are to be found on rotten stumps of trees and by supplying them with suitable pabulum—Badhamia feeds on a certain fungus (*Stereum hirsutum*)—you can actually cause the plasmodium to move towards the pabulum so that this movement can be readily observed with a low-power microscope and may, indeed, even be seen with the naked eye. Chemiotaxis was observed by these biologists, and later became a doctrine of cardinal importance in pathology with reference to inflammation and also with reference to a number of other problems connected with the invasion of the tissues by micro-organisms.

Human pathology, then, is greatly indebted to biology for at least those three fundamental facts. In addition to that, biology is so closely related to pathology that it affords its assistance in many other directions. In the first place, diseases are common not only in animals but also in plants, and many of the phenomena of disease such as are observed in the human subject—and even for the matter of that the phenomena of injury—may be observed with almost equal readiness in the case of plants, and in some instances plants afford a more suitable structure for the investigations of infections of various kinds than is the case in animal organisms. I mean that it is not always, perhaps, realised that plants suffer from infectious diseases of as complicated a nature and with as complicated a life-history, as regards the organisms causing them, as is the case with many morbid processes with which we are familiar in the human subject. Just as there are diseases in the human body dependent on parasitic invasion in which the parasite causing the disease in the human subject has to pass a portion of its life-history in some other host, so precisely the same phenomena have been found in regard to certain infective diseases of plants, more especially those dependent on mycotic invasion. There can be no question that the investigation of certain plant diseases is capable of throwing considerable light on some fundamental problems of pathology, such as the resistance of tissues to the irritation of foreign bodies and so forth.

The subject of animal diseases is a very large one and the relationship of these to man is manifold. Some human diseases no doubt may be contracted from diseases of animals and we have that problem before us at the present time with reference to the great question of tuberculosis, and especially whether tubercle in man and tubercle in animals are identical, quite apart from the question whether the human disease can be directly acquired from animals. You have a very much wider grasp of these questions by studying biology; for instance, a comparative study of tuberculosis in animals will enable one to get a very much wider grasp and very much more accurate knowledge of the nature of the disease than a study of it which is purely restricted to the phenomena as they occur in man In addition to that there are several instances in which the investigation of diseases in animals has thrown direct and immediate light on similar diseases in the human subject. I think that we are rather apt to forget, some of us, that the working out of the malaria problem and the relationship of the mosquito to the organism of malaria was after all not worked out first of all in human malaria but was worked out in the malaria of birds, and that it was with reference to the Proteosoma of birds—an organism somewhat allied to the organism of human malaria—that the part played by the mosquito was first decided. You could have no better instance of the very intimate relationship existing between biological problems and pathology, because after all it is purely a biological problem. It may be an important thing to man, but it is, so to say, an accident that malaria happens to be harmful to man. It is possible to go further than that and to point out another very interesting relationship between biological investigation and pathology still adhering to malaria in illustration. It is well known that in the case of some of these blood parasites affecting birds, particularly in the case of Proteosoma and of Halteridium, that some blood parasites do no particular harm to the bird in which they are parasitic and other closely allied forms produce illness in birds. We are not acquainted, as far as I know, at the present time with any protozoan blood parasite in man which is certainly benign, but at any rate we know from recent observation that the malaria parasite may exist in an apparently benign form in the blood of certain native races, and yet when transferred by the mosquito to the white man ill-effects are produced. There is a closely parallel instance in the case of the parasite of Texas fever in cattle where the organism may be present in the blood without producing ill-effects and yet produce the disease when transferred to other and healthy animals. There are certain flagellate organisms which live in the blood of rats, sewer rats, and which do no harm as far as we know, and there are certain other flagellate organisms of an allied kind which live in the blood of animals in India and South Africa which cause the fatal diseases of these animals known as "nagana," "surra," &c. A similar organism has been observed in the human subject in two, if not three, instances, and in one case causing disease in the human subject. The point to which I wish to draw attention is that we have evidence biologically that in the animal kingdom there may be apparently closely allied forms, the one existing in a benign and the other in a malignant form In some instances—as, for instance, in the case of the trypanosomata—this may be dependent *on* a different life-history.

I have said enough to show that the study of biology pursued entirely for its own end and with no idea at all of direct practical utility affords the medical student an opportunity of obtaining a very much wider grasp and knowledge of other subjects, and especially of anatomy, physiology, and pathology. I think that is enough to show the paramount importance of biology as a suitable science to provide an adequate mental training for the student of medicine.

A very few words now with reference to biology in relation to practice. The number of diseases which are now known to be definitely due either to animal or vegetable organisms is daily increasing and I need only allude here to blood diseases, for instance, various forms of anæmia in animals and in the human subject to the varieties of malaria, to such indirect blood diseases as the anæmia produced by various intestinal worms, more particularly ankylostomum, &c. The number of morbid processes which are due to the presence of fungi, especially actinomycoses, aspergillar mycoses, and blastomycetes, is increasing, and then the very large number of intestinal and blood parasites, some of great importance, others of comparatively trivial importance.

Such a subject as filariasis is apparently assuming more important relations and development, as an increasing number of morbid conditions have been shown, and are being shown, to be due to the presence of filaria. To take an illustration, there is a considerable amount of evidence to show that a number of diseases in hot climates which have been spoken of as malarial are not due to malarial parasites but may be dependent on the presence of various forms of filaria, and there has been a suggestion that some of the endemic diseases of South Africa, such as the sleeping sickness, may also possibly be due to blood parasites of that kind. When you think of all these diseases, many of them present in this country, others of them restricted to hot climates, I think that you will admit that the number of them is quite sufficient for it to be necessary for the practitioner to have a more or less thorough knowledge of these branches of biology. One could dilate at some length with reference to the use of biology in practice but I prefer to go on with the final heading of my subject—namely the relation of biology to research in medicine.

The relation of biology to research is shown in the remarks made just now with reference to Metchnikoff's work and one cannot help thinking that although the relation is now a close one it cannot fail to become much closer still From a strictly scientific point of view one must confess that medicine is but a branch of biology, but medicine is so large a subject in itself that it is convenient to classify it separately I think that the study of biology amongst other things brings us to the fundamental question of the nature of disease and one cannot help thinking that the progress of modern discovery, especially in the last 10 or 15 years, has to a very great extent altered our views, or the views of some of us, as regards the nature of disease. The part played by parasites, in the broad sense of the word, in the production of disease, not very many years ago, certainly less than a quarter of a century ago, would have been almost entirely limited to the intestinal tapeworms, whereas at the present day the question almost presents itself to one sometimes as to whether there are any diseases which are not of parasitic origin One must admit that there are certain injuries to the human frame where illness or death is dependent directly or remotely simply on the traumatism. One must admit that there are some diseases—as, for instance, myxœdema on the one hand and exophthalmic goitre on the other—where the fundamental pathological processes is an atrophy or an hypertrophy of some particular structures of the body. But really, if you put aside the traumatisms and the atrophies and the hypertrophies which are, after all, not very numerous, there are not very many diseases to which the human frame is liable which cannot be either directly correlated to the presence of a parasite or, at any rate, where there is not a shrewd suspicion that there is very probably a parasite I am quite aware that there are, of course, some morbid conditions brought about by chemical changes where it is unnecessary to assume the presence of any living parasite. There are some morbid conditions brought about by the ingestion of poisons—lead, for instance There are others in which very possibly the disturbing toxic chemical substance is produced in the organism itself, and it is, of course, probable, or at any rate possible, that there are certain diseases which may be entirely dependent on disturbed metabolism, such as diabetes. In many of these conditions and diseases where there is apparently a chemical agent at work (an auto-intoxication) it is quite possible that this is not really the proximate cause but that in addition there is a parasite and the toxic substance is elaborated by this parasite.

When we think that it is only some 20 odd years since the bacterial nature of disease was clearly determined and that it is a much less number of years (I do not remember the exact date at which it was observed) that certain diseases were due to fungi—as, for instance, actinomycosis—and that it is only within the last few years that the protozoa have been found to be pathogenic agents in disease, one cannot help thinking that the number of diseases which are dependent on parasites and which are therefore dependent on a proper study, knowledge of, and acquaintance with biology is an ever-increasing one. It is only some 21 or 22 years since Laveran made his discovery of the presence of the malarial plasmodium in human blood and it is only within the last few months, or last few weeks even, that trypanosomata—i.e., flagellates—have been discovered in the blood of human beings on the West Coast of Africa, so that, as I say, the relationship of biology to medical research brings one at the very outset to the fundamental question of the nature of disease. When we look at the number of blood diseases in animals, the number of different forms of hæmaturia and anæmia which are definitely known in the case of domestic animals to be dependent on the presence of parasitic protozoa, one cannot help thinking that sooner or later the same fact will be demonstrated in the case of many of the human diseases of similar character. There are human diseases which greatly resemble in their clinical symptoms and pathological anatomy these diseases in animals and in a number of such human diseases organisms of this kind have been already described by certain authorities, although not accepted by all.

In considering, then, the relation of biology to research we are often brought at once face to face with the question of the nature of diseases and at the present day one cannot help alluding to the question which is present in the minds of many as regards the nature of cancer. It may be a somewhat heterodox opinion for a medical man to mention here but one cannot help thinking that whatever the nature of cancer may be a great amount of light will be thrown on that question by the researches of the pure biologist rather than by those of the human pathologist, and it would seem that if the question of cancer is to be elucidated it must be necessary to investigate two sets of facts, both of which are of fundamental biological importance. The first is the question whether the organisms described by so many in the case of cancer are the actual cause of disease and what is their exact nature, because no biologist has yet been able to arrive at any certain conclusion as to the biological position of these structures. That is one side of the cancer question and it is certainly a biological one, and another side of the cancer question in which the human morbid histologist may follow the lead of the biologist is the investigation of the minute histology of the cell which, notwithstanding the very large amount of work which has been done in human morbid anatomy, has been scarcely touched. The biologist has worked out with much assiduity not only the structure but also the relationship of the centrosome and of the nucleus to the cell protoplasm. A number of minute points of that kind have been worked out with very great detail in the case of infusoria and sponges, and also in the case of a number of the lower forms of life, but in the higher forms of life, and certainly in the case of morbid anatomy, these have scarcely been touched. There are some observers who hold the view that the nature of cancer is intimately associated with the question as to whether it is dependent on a deranged function of the cell, an anomalous condition of the cell, associated with nuclear and centrosomic changes. There are some writers who have said that the structures that have been described as parasites are nothing more nor less than these anomalous centrosomes. I mention this as an illustration, to my mind, of the problems, the very pressing problems, in human pathology which for their solution at any rate require the aid of the biologist, and, indeed, may perhaps receive their solution from him. These are all somewhat discursive remarks as regards the relationship of biology to the nature of disease.

Another biological doctrine of great interest to the human pathologist is the question of variation and the influence of environment—that is a biological doctrine of very great importance and it is also of great interest to the medical practitioner and student. When we consider problems such as whether bacteria may be saprophytic and then in certain circumstances become pathogenic—that is, practically speaking, a kind of variation. The facts of a total different order that I have already mentioned about the plasmodium of malaria existing in the blood of native races without causing any disturbance but on being transferred to the white races causing malaria—that, I should think, is also a fact of a closely related character. These illustrations will be sufficient to show that even such a question as variation, a highly technical branch of biology, has its relationship to the medical practitioner.

We come finally to one of the most vexed questions in biology which certainly is of great importance in human pathology and human medicine and to all of us, and that is the question of heredity. You cannot open a text-book of medicine without getting the most diverse instruction with reference to the part played by heredity in disease, and there can be scarcely any subject of more interest to the human race than an adequate and sound knowledge of such an important subject as that of heredity. Problems of heredity are, I think, scarcely to be settled by statistics as regards the incidence of disease in ascendants and descendants. It is, of course, to Weismann that we owe many of our fundamental and modern views on this subject. One of the most important conclusions is that acquired characters are not transmitted and that the only things which are transmitted are the characters of the germ plasm. That is a doctrine which must be of wide-reaching and very great importance to the pathologist and the medical student and one which perhaps in the present day has not attracted the notice that it deserves. Weismann, you will remember, was led to these far-reaching deductions by a close study of the duration of life in a great variety of forms, beginning with his conclusions that the amœba, or rather the protozoa, as far as is known, are the only immortal animals. He showed that in these low forms of life death was not by any means a necessary phenomenon of life, but was, so to say, an accident; in the higher forms the germ cells did not die. And from that he led us to the doctrine that acquired characters were not transmitted. From that he was led to the conclusion which is of most importance to us as medical students—namely, that impairment or mutilations of the parent or changes of health in them could not act directly and specifically on the germ cells; all they could do would be to increase or to diminish the vitality of the germ. To take a stock illustration, the fact of the parent acquiring a tuberculous disease could not by any possibility cause the germ plasm to become tuberculous except by direct infection and all it could do at the utmost would be to weaken the germ plasm so as to make it less resistant to the tuberculous and other invasions. This doctrine of Weismann as regards heredity and the whole question of germ plasm are matters of fundamental importance not only to the practitioner but to the student and to the pathologist, and it is of interest that Weismann's conclusions were arrived at from a study of purely biological phenomena and have received a very striking confirmation in the work of a pure pathologist—I refer to Dr. Bulloch You are all familiar with the fact that if the blood of one animal is introduced intra-peritoneally into another animal the blood of the second animal develops certain properties after receiving the blood of the first animal. If you inject into the peritoneum of a rabbit the blood of an ox the blood of the rabbit acquires properties by which it hæmolyses the corpuscles of the ox Dr. Bulloch made use of that fact in studying certain phenomena of heredity and he has shown that supposing a male rabbit's blood is made highly hæmolytic to ox's blood that the descendants of that male rabbit derived from a normal female have no such power, but that, on the other hand, if the blood of a female rabbit is made highly hæmolytic with the blood of an ox then the descendants of the female rabbit after connexion with a normal male have blood which is highly hæmolytic—in other words, the properties acquired by the mother are apparently transmitted but not through the germ plasma, only by the interchange possible owing to the placental circulation. You will say that there is nothing new in this and that the same facts are known in relation to human small-pox and human rheumatism and endocarditis. The same argument may be adduced with reference to the facts of cerebral localisation. We might say that we knew all about cerebral localisation as a result of Dr H Jackson's masterly deductions from the study of epileptic convulsions, and that we did not need Hitzig and Ferrier's work. There is a very great difference between the precision of a result that has been obtained by an experimental method and the results of a statistical method. This confirmation by Dr Bulloch's work of a certain part at any rate of the work of Weismann is I think, a point of very considerable interest to us all.

Biology in relation to research, quite apart from the investigations of any particular disease, is of great interest and importance from at least these three points of view Biology ought to be of interest to all of us, because if Darwin's views are correct we are all of us more or less engaged in trying to upset one of the fundamental laws of the universe, because, as a physiologist said not long ago, the function of doctors and the function of hospitals is to promote the survival of the most unfit and, therefore, if for no other of the reasons which I have brought before you I think for that final reason the study of biology ought to be regarded as full of interest for you all.

Finally, I will only say that quite apart from the relationship of biology to medicine the study of biology is one of the most charming hobbies apart from any direct bearing on our professional work that a medical man can engage in.

The Ingleby Lectures

ON

CHRONIC HYPERTROPHY OF THE FAUCIAL AND PHARYNGEAL LYMPHOID OR ADENOID TISSUES.

Delivered at the University, Birmingham,

BY F MARSH, F.R.C.S. ENG.,

SURGEON TO THE QUEEN'S HOSPITAL AND LATE SURGEON TO THE EAR AND THROAT HOSPITAL, BIRMINGHAM

LECTURE II.[1]

Delivered on June 3rd.

MR. DEAN AND GENTLEMEN,—The discovery of adenoids was primarily due to the application of the principles of the laryngoscope to posterior rhinoscopy. Although not the originator of the idea Czermak was the first practically to apply the method in 1859 and the first to see adenoids in 1860, when he published an account of a case where he had observed two small tumours on the upper part of the naso-pharynx on the left side close to the opening of the Eustachian tube, one portion of which somewhat resembled a "cock's comb." He failed, however to grasp the true importance of the condition, as did Voltolini, though to a less extent, some five years later, when in 1865 he perceived with a rhinoscopic mirror stalactite like growths projecting into the free cavity of the naso-pharynx. The patient, a man, aged 41 years, was under treatment for extreme deafness, which improved after the application of the electric cautery to these growths. In the same year Löwenberg published three cases of patients suffering from deafness who had a condition of the naso-pharynx similar to a granular pharyngitis. In England Andrew Clark, in the London Hospital Reports for 1865, gave a somewhat similar account of this condition in a short article on Nasopalatine Gland Disease and called attention to the presence of "fetid cheesy masses" which, he thought, *were contained in the cavities of the glands.* It was however, reserved for Wilhelm Meyer of Copenhagen in 1868 to realise the clinical importance and to give a more accurate and complete history of the condition and the name "adenoid vegetations." He made a careful microscopical examination of the structure and detailed methods of treatment. It is interesting to note that he made an examination of 2000 children in the National School of Copenhagen and discovered the condition in 1 per cent.—very different from the result of an examination recently made in England by Mr A. H. Cheatle of the ears of 1000 school children in the Hanwell District School, who found that out of 50 per cent. with middle-ear trouble no less than 38 per cent. had either adenoids alone or with enlarged tonsils. In 1875 Guye of Amsterdam read a paper on the subject at the International Medical Congress at Brussels and Löwenberg published a monograph in the same year. The subject was again discussed at the International Medical Congress in London in 1881, Capart of Brussels and Woakes of London taking a prominent part. This discussion was the means of directing general professional attention in England to the subject and I can remember the almost universal smile of unbelief which greeted its mention. This incredulity was hardly to be wondered at, as then to most surgeons the larynx and naso-pharynx—intrinsically—were *terra incognita*, and the methods of operating, especially with the finger nail, did not appeal to the surgical mind. Even in 1884 Sir Morell Mackenzie did not fully recognise the fact that these "adenoid vegetations" were a hypertrophy of Luschka's tonsil and analogous to the chronic enlargement of the tonsils. In vol. ii., page 490, of his book on "Diseases of the Throat and Nose" published that year, when writing of chronic catarrh of the naso-pharynx, he says "In young subjects adenoid growths are sometimes present or there may be simple enlargement of Luschka's tonsil." His description of the appearance of adenoids, too, was not quite in accord with that of to-day, as in describing them on page 499 he says "As a rule they are rounded in form and vary in size from a hemp seed to a currant, but are occasionally much larger and often occur in clusters." In most other points he is however, singularly accurate. Not much advance was then made until Hartmann and Gottstein devised their ring knives or curettes. The introduction of the latter about 12 years ago rendered removal *en masse* practicable and so gave in most cases a specimen representing the actual condition instead of a number of small fragments. The frequent inspection of such specimens undoubtedly conduced to the exact knowledge which we hold to-day.

Adenoids vary in size from a small localised patch to a mass filling the naso-pharynx. Their consistence is at first softer than that of enlarged tonsils owing to a preponderance of the lymphoid over the fibrous tissue, but at the age of puberty fibrous atrophy more or less takes place and the consistence becomes more dense. This atrophic process is not invariable, as not infrequently adenoids are found retaining their soft lymphoid condition long past the age for the fibrous change. Although there is so much difference in the size and shape of adenoids it is very difficult satisfactorily to classify them. Normally, according to Lermoyez, Luschka's tonsil "consists of from four to six parallel bands, delineating a series of concentric arcs which converge behind and in front like the lips of a vulva. When hypertrophied these bands form the same number of small tongues, parallel posteriorly, and placed together after the fashion of the leaves of a book. In the recesses which separate them the muco-pus accumulates retained by the inflammatory adhesions which partially solder their lips together and form enclosures. This arrangement of parallel ridges and furrows or recesses obtains in most cases where the hypertrophy is at all marked but varies considerably in degree. At one extreme the ridges or bands are smooth and rounded and the recesses shallow and even, the surface admirably showing the parallel arrangement, at the other extreme the recesses are deep, sometimes converted into cavities containing mucoid or caseating material and the ridges are ragged and uneven almost stalactite-like at first sight, but when examined maintaining the above form. Between these extremes a large number of cases are found. When fibrous atrophy has taken place the surface is often left serrated and pitted and occasionally small but distinct cavities opening on the surface are seen. The so-called Tornwaldt's bursa is simply one of the central recesses partly converted by adhesions into a cavity. In some cases a portion only of these concentric bands hypertrophies and an uneven surface results—void of definite arrangement and involving either the central or lateral regions of the naso-pharynx or both. In these cases the lateral pharyngeal bands and the scattered patches on the posterior wall of the pharynx are often enlarged. Bearing these points in mind the following classification might be made: (1) a central form comprising (a) the ordinary form concentrically arranged—already described—with little or no lateral hypertrophy and (b) a central boss or pad, the prominent symptom being impeded nasal respiration; (2) a lateral form with hypertrophy of the lateral bands most marked and often extending into the fossa of Rosenmüller, deafness being the prominent symptom; and (3) a diffuse form with a general and irregular hypertrophy of all the lymphoid tissues in the naso-pharynx and pharynx, seldom attaining any great bulk, the prominent symptom being catarrh. The symptoms, however, depend almost as much upon the size as upon the position of the hypertrophy. They may be arranged in three groups—(1) obstructive, (2) catarrhal, and (3) reflex. 1. The obstructive symptoms are caused mechanically by the enlargement wholly or in part occluding the openings into the nares and Eustachian tubes and causing nasal obstruction and deafness, and a muffled or "dead" voice. 2. The catarrhal symptoms are due to the great suitability of the recesses as nesting places for the catarrh microbe—even more so than in the case of the tonsil. With any diminution of tissue resistance the microbe gets the upper hand. The attack may remain a localised one, causing adenoiditis and temporarily increasing obstructive symptoms, or it may extend to the nasal regions causing rhinitis, along the Eustachian tubes to the middle ears setting up an acute or subacute catarrhal condition with myringitis, or it may travel downwards to the tonsils, larynx, trachea, bronchi, or gastro-intestinal tract according to the degree of tissue resistance and predisposition of the child. There is a great tendency for these attacks to become chronic and difficult to cure. Toxin generated by the microbes may be absorbed by the lymphatics and cause enlargement and tenderness or suppuration of their associated cervical glands—the parotid set—just as in the case of the tonsils. 3. Reflex symptoms are more often due to adenoids than to enlarged tonsils. Instances of headache, cough, spasm of the glottis, asthma, and sneezing have come under my notice. More remote ones—convulsions, epilepsy, stammering, and incontinence of urine—have been attributed to adenoids, but I cannot recall any case in my own experience that I could definitely put down to them. The following cases are instances.

---

[1] Lecture I. was published in THE LANCET of June 7th, p. 1587.

CASE 1.—The patient, a girl, aged 15 years, was brought to me on May 7th, 1901, for daily frontal headaches. She was unable to breathe through her nose during sleep, which was never refreshing, and she was slightly deaf with colds. On examination she had marked adenoids. Their removal under ethyl chloride afforded complete relief.

CASE 2.—A child, aged four and a half years, was seen by me with Dr. B. F. Jordan on May 19th, 1901, for attacks of spasm of the glottis, which commenced on May 15th, a sequel of a catarrhal tonsillitis and adenoiditis. In August, 1899, some 18 months previously, she had been operated upon by a surgeon for enlarged tonsils and adenoids causing obstruction to respiration. The spasms were very severe and alarming and a trained nurse had to be with the child at night. On examination both tonsils were hypertrophied, especially the left; the surface was very ragged and there was evidently a recurrence of the adenoids. As the catarrhal condition had subsided and the child was otherwise well operation was advised and it was performed on the following day; a large mass of adenoids was removed with the bulk of the tonsils. There was no return of the spasm and the child has been strong and well since.

CASE 3.—A boy, aged 12 years, was brought to me on account of frequent catarrhal and asthmatic attacks which kept him indoors at home most of the winter. There were no obstructive symptoms but adenoids were found to be present on rhinoscopic examination. These were removed on Jan. 8th, 1901. His mother informed me a few months ago that he had been quite free from asthma since.

CASE 4.—A child, aged about six years, was sent to me by Dr. G. Haddow for incessant sneezing—every few seconds—except during sleep. She was not a neurotic child but was very placid and tractable, and she allowed a thorough inspection of both nose and throat. Her tonsils were enlarged and adenoids were present, but I was inclined to think that the reflex must be due to some intra-nasal irritation although I could not find any hyper-sensitive area. I therefore applied trichlor-acetic acid to the upper area of the septum nasi on both sides and ordered a menthol ointment. This made no difference, so about a week later, as the child was becoming exhausted, a tonsil and adenoid operation was performed. This was immediately followed by complete cessation of the sneezing.

Adenoids if neglected often seriously affect the development of the oro-nasal regions, the thorax, and that of the body generally. The development of the posterior nares is sometimes arrested, probably where adenoids have been present at birth or quite early in life. I have noticed that in some cases the arrest has been more marked on one side than on the other. The naso-pharynx in these cases is generally similarly affected, being shallow and small. In some cases, on the contrary, the adenoids seem to have an expansile action, and alter the shape of the posterior nares, the upper margin losing its ovoid character and becoming angular like an inverted V. The adenoids occupy this angle and increase the nasal obstruction. This condition is most often found in older children—from 10 to 16 years old. More rarely the growth of the soft palate is impeded, and when the adenoids are removed it cannot be approximated to the posterior wall of the pharynx, consequently the voice after operation is of a very nasal character. One such case has happened in my practice in a girl, aged seven years, who was operated on some years ago. The cleft palate kind of voice was most disagreeable and a source of anxiety to the parents. I heard a short time ago that the voice had improved but little. The anterior nares and nasal meati are often narrow and the alæ nasi collapsed—from disuse and atrophy of the dilator naris.

When nasal stenosis to any marked degree exists the growth of the superior maxilla is much interfered with and assumes an almost characteristic shape. The hard palate becomes high and arched, narrowed in front almost to a point—the V-shaped jaw. As a result the teeth have insufficient room, the upper incisors overlap, and the canines are crowded out, appearing in front or behind their proper position. The excessive arching tends to diminish still further the lower nasal airway. The mouth is constantly open and the upper lip is drawn up, leaving the upper incisor teeth uncovered. Narrow nostrils with marked depression round the alæ nasi, open mouth displaying overlapping teeth, and drooping lower jaw combine to make an almost typical facial appearance. The teeth, too, from constant mouth breathing seem more prone to caries, alveolar abscess, and chronic pyorrhœa. The effect on the thorax, especially when enlarged tonsils co-exist, is very marked; the lungs are never properly expanded, the thorax remains narrow and contracted, the cartilages of the ribs fall in on each side of the sternum, and the lower piece of the sternum is drawn inwards by the action of the attached fibres of the diaphragm. The child is pigeon-breasted with a deformed sternum. The general development of the child is bad; it is stunted in growth and has little muscle power. From this cause it is, given a slight exciting cause, much more liable to acquire such deformities as lateral curvature of the spine. The sleep of these children is seldom good; they are restless, turning about during half the night with the bed-coverings thrown off, and the neurotic type are the victims of frequent night terrors. The mental condition is also often unsatisfactory, especially when both nasal obstruction and deafness are present. The child becomes listless, capricious, irritable, inattentive, unable to concentrate his attention upon his lessons, and if possessing the typical facial aspect looks stupid and vacant. Slow, if any, progress is made in education and the child is often punished for inattention, though perhaps less so now that many teachers are fully alive to the possible cause. This condition was attributed by Guye of Amsterdam to interference with the lymphatic channels passing from the meninges to the nasal fossæ and termed "aprosexia," but no anatomical evidence in support of his view was adduced. I have myself only seen these cases of "aprosexia" in association with deafness and nasal obstruction, which are quite sufficient in themselves to cause the condition. A limited hypertrophy only would block the lymphatic channels and the condition would be almost universal instead of limited to a certain group. In the majority of cases the history given is that the child has the mouth constantly open, snores at night, frequently catches feverish colds, is then somewhat deaf, complains of earache, and does not "get on" well, and, as Lermoyez graphically points out, is always being told to shut the mouth and blow the nose—the two things that cannot possibly be done. The mother or a friend has often now diagnosed the condition in advance, and the diagnosis is not only made in drawing-rooms of mansion or villadom but in the doorways of byways and courts. It is a common thing for a child to be brought to the hospital to have "them things" taken out of his throat, as he is just like Mrs. Somebody's child who has recently had his "took out" and inferentially improved thereby. A difficulty which the to Maidstone, and on this point Dr. Washbourn said in his report that '*no importance can be attached to the failure to discover the typhoid bacillus in water suspected of being the cause of an epidemic of typhoid fever.*' If this is so, it is still less likely that the typhoid bacillus would be found in water which is merely suspected of producing typhoid fever in those persons of the community who are peculiarly susceptible to it. In fact, the test which shows whether a water contains typhoid poison is not the discovery in it of the bacillus of the disease, but the fact of its producing or not producing that fever among the people who drink it.

"Sir Wm. Crookes and Professor Dewar allude to the Maidstone inquiry and say that 'it was proved beyond all doubt that one of the sources of supply had been *grossly contaminated with fæcal matter.*' The Local Government Board inspectors who conducted the inquiry came to no such conclusion; they merely say that the water sources 'were all exposed *to the risk of* pollution' and they add 'there is *no conclusive evidence* to show either how the specific pollution of typhoid fever was introduced into the supply, or which of the springs was thus polluted.' (The italics are mine.)

"As to the chemical evidence of pollution of the Maidstone water I have before me the table of analyses of the water referred to, and find that out of 22 samples examined five showed signs of organic contamination. In one sample this contamination was rather greater than in the samples of water supplied to St. George's, Hanover-square, last December, *but not greater than in samples that have been supplied on other occasions*, but in the other four it was less, and in all of them the results of analysis tend to show that the organic matter was 'chiefly of vegetable origin.'

"*The organisms found by Drs. Sims Woodhead and Washbourn in the Maidstone water were* of similar kinds to those found by Drs. Parkes and Rideal in the waters supplied to Chelsea, and, as already stated, the typhoid organism was not found in any sample.

"The company's analysts go on to say 'there is no comparison between the conditions of the polluted spring water-supply which originated the Maidstone epidemic and *any polluting conditions which* can arise in the Thames Valley, where strict supervision of all sources of contamination is so efficiently maintained,' a conclusion diametrically opposite to that arrived at by the Public Health and Water Committees of the London County Council, who say in their report: 'We consider that in respect of physical conditions the causes which led to the typhoid epidemic in Maidstone have a parallel in the conditions of the London water-supply. The epidemic was caused by water drawn from polluted sources. It is admitted, and the facts above quoted conclusively show, that the water supplied to London is also derived from sources liable to become polluted. As Sir Alexander Binnie points out: 'This is but another instance among many which teaches the general lesson that *for many years* a population may be supplied with water from various sources without any apparent harm to the consumers and that the water so taken has been repeatedly pronounced after chemical examination to be pure and wholesome, but that if the water is derived from a source liable to pollution sooner or later the time generally arrives when an epidemic breaks out owing to circumstances connected with the pollution of the supply.'

"In this connexion the following remarks of Dr. Clowes, the council's chemist, are worthy of attention: 'While there are grounds for believing that the comparative immunity from typhoid fever which is enjoyed by the consumers of London water depends largely on the effective working of the filters, it must be understood that a breakdown in the filtering arrangements might possibly, at any time, produce a serious epidemic. And although the ordinary process may remove 90 per cent. of the bacteria which are at present in the river water, it is reasonable to suppose that the remaining 10 per cent. of the bacteria may occasionally number in their midst the bacillus of typhoid fever.'

"As Sir William Crookes and Professor Dewar refer to their 'extensive experience,' I may be permitted to remind you that I have reported on the water supplied to St. George's, Hanover-square, for the last 25 years, and with regard to their remark that I seem to entertain a different view of the origin of typhoid epidemics from that generally held, I may mention that I have seen some hundreds of cases of typhoid fever and investigated some thousands in this and other countries during the past 30 years; that 25 years ago I combated the then prevailing opinion, advanced by Dr. Murchison, that the poison of the disease was produced by the decomposition of fæcal matter, that, in fact, it originated *de novo*; and that I have for a long time past come to the conclusion, which many others share with me, that typhoid fever spreads in other ways than by the pollution of drinking-water.

"I am, nevertheless, of opinion that such other ways are not competent to account for the increase of typhoid fever in London during the winter months, when it ought to diminish, and that there is in all probability some connexion between this increase and the fact that the greater part of London is then supplied with water which contains 'an excess of organic matter.'

"I will also add that it is at any rate a remarkable coincidence that I am able this month to report to you that *the number of cases of typhoid fever in London has very considerably diminished* and the death-rate from it gone down to its normal amount now that the water-supply has ceased to show the signs of contamination to which I have drawn attention." (April 11th, 1899.)

To this no further answer was received from the advisers of the water companies.

Mr. Shirley Murphy, in his annual report for 1894 as medical officer of health of the London County Council, drew attention to the fact that the distribution of cases of enteric fever in London "was characterised by the increase of prevalence in the forty-ninth, fiftieth, and fifty-first weeks," and that this late outbreak was exceptional and "was observable in the population supplied by all the London water companies except the East London and the Kent Companies. Also that the water supplied from the Thames and Lea was polluted owing to the fact that severe floods had occurred in November." He also states that: "Inquiry as to the behaviour of enteric fever in populations in the vicinity of the county gives indication of some difference of behaviour of this disease in the population supplied by water from the Thames and Lea and in the population otherwise supplied, the population supplied from these rivers experiencing an increase of disease in the forty-ninth, fiftieth, and fifty-first week, corresponding with that experienced in London. The hypothesis of water-borne contagion appears better able than any other to afford explanation of the increase of disease in the weeks in question."

I have no doubt from the above facts that the unseasonable prevalence of typhoid fever in November and December in London is due to the distribution of *inefficiently filtered* river water containing the poison of the disease, in sufficient amount, however, only to attack the most susceptible persons among the population.

Dr. S. Davies, the medical officer of health of Plumstead, reported in 1893 that the cases of enteric fever among the men employed in the Arsenal were caused by their habit of drinking water used for an engine and drawn from the Arsenal canal. This water is liable to be polluted with the excreta of labourers and is very liable to contain the infection of enteric fever. This reminds me of the account given by Dr. de Renzy of the prevalence of typhoid fever at Millbank Prison when it was supplied with water drawn direct from the Thames. On supplying the prison by means of an artesian well the disease became as rare there as it was frequent before.

In not a few instances—and some of them very important ones—the water-supply has become polluted while in the mains, whether on constant or intermittent service, by the specific poison of typhoid fever and serious outbreaks have been caused by it. Some of the more remarkable of these are the following. At Lewes (Sussex) Dr. Thorne reported in 1874 that there was a "large epidemic of enteric fever *due in the first instance to pollution of the town water-supply* from water drawn from the Ouse, which receives the town sewage, and mainly spread by suction of polluting matter into the water-pipes of an intermittent water service" (Report of the medical officer of the Privy Council and Local Government Board, New Series, No. IV., for 1874). He also reported as follows on an outbreak at Wolverton: "Water-supply exposed to risk of pollution by suction of foreign matters from closet-pans into mains of an intermittent service" (Report of the medical officer of the Privy Council and Local Government Board, New Series, No. VII., for 1875). And on another at Tideswell, Derbyshire: "Spread of disease favoured by conditions in an intermitting water surface allowing of suction of foul air into water-pipes" (Sixth Report of the medical officer of the Local Government Board for 1876). Dr Thorne also reported on an outbreak in the Dewsbury registration district as follows: "Water-supply for some districts liable to pollution at its sources and periodically fouled in delivery mains during intermissions in the service." And again in the Dewsbury Urban Sanitary District: "Water-supply subject to pollution at, and probably on its course from, the gathering ground. Supply intermittent and liable to be fouled by suction of filth into mains (*Eighth Report of the medical officer of the Local* Government Board for 1878).

In 1874 Dr. F. R. Blaxall reported on an outbreak at Sherborne (Dorset) as follows: "The influence of milk in the distribution could be excluded, but respecting the circumstances of the water-supply the following facts were ascertained. During December, 1872, and January, 1873, the water was frequently shut off from the town at a point near to the reservoir and the same thing was done every night in February. It is known that when the water was shut off there were certain delivery pipes up which there was a rush of air immediately the tap was unscrewed. Now many of the openings to the pipes are situated in the pans of the water-closets. At night, after the closet had been used, the tap would be turned on for the admission of water; none flowing, the tap, in many instances, would not be turned off again; thus, a direct passage into the water mains would be left open, but the accidental circumstance of leaving the tap open was not required as many taps were broken and admitted a continuous flow of water during the day but at night, no water being present, were uninterruptedly open to sewer air. Through these openings during the night air commonly passed from the closet-pan to the water-pipe; in other words, the system of pipes for the water-supply became the means of ventilating the closet-pans; if a trap happened to be broken or out of order it became a means of ventilating the sewers, and if a pan happened to be full of excrement, specialist has to contend with now is to convince some parents that adenoids are not the cause of their children's deficiencies, and I intuitively feel that occasionally they go away unconvinced and will not rest until they have found someone who will take a view in accord with the opinion of the lay authority who first implanted the idea that the slight mental or physical imperfection is due to adenoids.

Although in most cases the symptoms alone are fairly conclusive, a careful examination, including the anterior nares and the ears, should always be made. I have seen one or two cases of deafness attributed to adenoids, due simply to an accumulation of cerumen. The presence or absence of incurvation of the drum is an important diagnostic point. Whenever there is deafness it is a good plan to inflate the middle ears with a Politzer air bag, both to show how much of it is due to defective aeration and to enable a more reliable prognosis to be given

Nasal obstruction, from hypertrophic rhinitis, deflection of septum nasi, mucous polypi, &c., or more rarely from a naso-pharyngeal polypus, sarcomatous growth, or meningocele, forms the common source of errors in diagnosis. I have only met with one case of meningocele, which occurred in my hospital practice, and was diagnosed by digital examination and under general anæsthesia, and two or three cases of sarcoma of the naso-pharynx. Some of these conditions, all in fact but naso-pharyngeal ones—may coexist with the adenoids, and if not recognised and treated may prevent the full success of the adenoid operation. Having eliminated causes of error in ears and anterior nares, the naso-pharynx should be examined to make the diagnosis absolute. Digital examination should *not* be the routine method. It is very unpleasant and alarming and is only called for in the few badly trained and unmanageable children who make any other method out of the question and in a few with an excessive tongue reflex. I have to employ it now in a very small percentage of cases. My experience with children is that they are quite as tolerant of examination by posterior rhinoscopy as are adults, and that, as a rule, there is no difficulty in obtaining a sufficient view of the naso-pharynx with a small mirror to show if adenoids are present. In estimating the size of adenoids by this method it must be remembered that they appear much less than they really are owing to the necessary obliquity of the rays of light reflected from the mirror The size of the tonsils is sometimes an impediment to the introduction of the mirror, but when this is the case adenoids are almost certain to coexist, and as *tonsillotomy* is necessary the question can be determined and dealt with when the child is under an anæsthetic for this purpose.

The diagnosis having been made absolute, the next and all-important question is that of treatment and this is determined by the symptoms rather than by the actual size of the adenoids Is an operation necessary or advisable or may the case be treated by other and milder measures? Operation is in my opinion necessary or advisable for any one of the following conditions (1) aural symptoms—deaf mutism, catarrhal or suppurative middle ear trouble, and temporary deafness from defective middle-ear aëration, (2) distinct nasal obstruction, especially if impeding development, (3) frequent and chronic catarrhal attacks interfering with health and education; (4) cervical adenitis associated with adenoiditis, and (5) reflex conditions unrelieved by treatment for which there is no other apparent cause It is often advisable for improvement of the singing voice in older patients apart from other symptoms. Milder measures may be adopted, when both adenoids and symptoms are slight in children near the age of puberty—when fibrous atrophy may soon take place and the nasal cavities enlarge—and should be adopted for cases where symptoms are absent although adenoids are distinctly present. In these cases cleansing and astringent solutions may be applied locally, with irrigator, spray, or brush. Borax and salt, five grains of each dissolved in two ounces of warm water, is an unirritating and simple wash. Carbolic acid should not be routinely used, as it tends to impair the sense of smell. After the wash an astringent spray should be used (post nasal) of chloride of zinc, glyc. tannic acid, hydrastis, alum &c., as strong as can be tolerated, or the solution may be applied directly by means of a cotton wool applicator in the more tolerant children. Internally iodine, iron, cod liver oil, and hypophosphites are the standard remedies. It is in these cases, too, that systematic nose-breathing exercises may be employed with a reasonable expectation of benefit. A sojourn at the seaside or on moorland will often do more than all these remedies and will be much pleasanter to the patient.

It is instructive to follow the history of the operation The galvano-cautery was applied by Voltolini and *others* in a very vague manner to a few cases before the clinical significance of the condition was recognised, but the first definite attempt at complete ablation was made by Wilhelm Meyer with the ring knife devised by him. This was passed through a nostril and forcibly applied to the adenoids with or without the guidance of a finger in the naso-pharynx The shank of the knife was flexible and could be bent to any desired curve This method, suitable though it might be for slight diffuse adenoids, must have been very unsatisfactory for those of any bulk—in fact, I should say that it was impracticable thoroughly to ablate them. This difficulty must have been generally felt, for about the same time Löwenberg and Solis Cohen devised forceps for introduction through the mouth into the naso-pharynx. With these small bits of adenoid tissue were cut or pulled out, the procedure taking a considerable time. About this time the finger nail was advocated, and, I regret to say, adopted, by some English specialists. The crushing and hæmorrhage would perhaps produce some temporary improvement, but a satisfactory result would only obtain in those slight cases where an operation was not needed To assist those with a weak and feeble finger-nail Capart devised a steel one—doubtless less septic and more effective but never efficient. Numerous varieties of forceps now began to appear, apparently almost every specialist deemed it incumbent to devise an instrument or to modify and to endow someone else's with his name An advance in the technique was made by first removing as much as possible with forceps and then applying the steel nail to clear the surface of débris—thus leaving it less ragged. Hartmann's ring knife or curette marks the next advance. It was not altogether unlike Meyer's altered and adapted for use through the mouth The cutting edges were on the upper and posterior surfaces. After introduction behind the palate the blade was passed along a lateral wall of the pharynx until the vault was reached It was then pressed against this and the posterior wall and swept a few times from side to side, care being taken not to give the blade a lateral deflection This, either alone or preceded by the use of forceps, was the quickest and most satisfactory method until the introduction of Gottstein's ring knife a few years later This differed from that of Hartmann in being shaped to cut through the adenoid tissue from before backwards instead of laterally It gradually took the place of Hartmann's, but, like the forceps, it has been the source of many modifications, chiefly in the curve of the shaft and the inclination of the cutting edge. Of other instruments an adenotome made after the principle of a tonsil guillotine has been devised by Schutz, but though ingenious it is only suitable for central masses of fair size and it has never come into popular use. Trautmann's curette is practically a Volkmann's spoon with a suitable curve in its shank and is suitable only for scraping small diffuse patches in adults. The same may be said of the galvano-cautery, although several ingenious curette loops and points have been devised. The cold wire snare is, in my opinion useless and should never be used

The apparent simplicity of some of these methods was mainly responsible for the idea that invaded the minds of the profession that removal of adenoids was devoid of risk and could be undertaken without any special experience. The result of this was shown by the publication of statistics in 1896 reporting 11 deaths in England alone in a little over two years during operations under chloroform for removal of adenoids and enlarged tonsils, and by a decided increase in the number of disappointing results from incomplete operations

The mortality of the operation should be *nil* and probably would be if both the anæsthetist and the operator had special experience or even if one only had experience A skilled anæsthetist will steer the inexperienced operator safely through the operation, and a skilled operator will prove a safeguard to the inexperienced anæsthetist. It is the combination of inexperience that produces the mortality

Incomplete operations—much to be deprecated, as they bring a most useful operation into discredit—are due chiefly to want of method Using forceps or scraping with a curette hither and thither without method until no more tissue comes away is neither a desirable nor an efficient procedure. An anæsthetic should always be given. In children I prefer chloroform given by the open method, by which I mean dropping chloroform from a drop-bottle on to a *single* fold of towel, flannel, or lint, shaped to fit over the mouth and nose after Lister's plan, or stretched over a mask like Schimmelbusch's. The drops should be gradually increased in frequency and should cover a greater area of the lint, until the conjunctival reflex is quite abolished. At this stage the laryngeal reflex is unaffected, and there is no danger from suction of blood or débris into the air-passages, whilst ample time will be given for the operation. Should further administration be necessary—which should seldom be the case—the back of the throat must be well mopped out with lint swabs and the face turned well to one side, so that any blood may run out of the mouth. Care is needed now not to press the anæsthetic unduly, as it is more important than before not to interfere with the laryngeal reflex, as blood-clot formed in the interval in the naso-pharynx may easily be drawn into the larynx and air passages. I have never had a death or witnessed one at this operation, but I think it highly probable that some of those reported may have been due to this cause. If preferred by the anæsthetist ether or ether and chloroform may be given, either by the open method or inhaler, the same precautions being taken. To older children and adults nitrous oxide gas may be given if the case is a simple and uncomplicated one. The drawbacks to it are that one cannot tell beforehand quite what length of anæsthesia will be obtained, and in some cases jactitation causes difficulty and delay. In the majority of cases there is sufficient time for a thorough clearance to be made. Gas and ether will afford much more time and may be employed if it is thought that extra time may be wanted. An experienced administrator is a *sine quâ non*.

Kelene or ethyl chloride bids fair to supersede gas. It has been administered for me by Dr. W. J. McCardie in 20 cases, chiefly those of young adults. It has given on the average about two minutes of anæsthesia and analgesia. Its advantages over gas are the longer time given and the absence of congestion and cyanosis. Recovery from its influence is quite as rapid and the patients are able to walk back to bed. No troublesome after-effects occurred in my own cases. When it has been more extensively used I believe statistics will show it to be much safer than chloroform or ether. No death from it has as yet occurred in this country and it must have been given to approximately 1000 cases. The following table of 1000 cases shows the number of chloroform and gas administrations to children 16 years old and under.

Table showing the Number of Administrations of Gas and of Chloroform to Children 16 years of age and under in a Series of 1000 Cases

Age.	Gas.	Chloroform.	Number.
In the first year of age ..	—	8	8
,, second ,, ...	—	17	17
,, third ,, .	—	48	48
,, fourth ,, ..	—	74	74
,, fifth ,, ...	1	104	105

	196	619	815
Over 16 years of age	—	—	184
One case—14 weeks old—no anæsthetic ..	—	—	1
Total	—	—	1000

After trying many methods of operating I have adopted the following as being both rapid and efficient. The patient is placed in the recumbent position, with the head and shoulders slightly raised on a low pillow. I have adopted this in preference to "the head over the end of the table" position, finding that the hæmorrhage is less and not a source of trouble, whilst the head is steadier and in a better position both for the anæsthetist and the operator. The desired stage of anæsthesia having been reached the mouth is opened with a suitable gag on the left side. A large-size slightly curved Gottstein curette is introduced behind the palate, the handle being held firmly in the fist—dorsum upwards—and not as a scalpel or pen; the blunt edge is kept well against the septum and passed upwards to the pharyngeal vault until slight resistance is felt by the cutting edge meeting the adenoids; firm pressure is made for a moment, and then a quick *tour de main* is made, taking the handle upwards and the blade downwards. This makes a clean section of the adenoid mass and brings it, if of any size, into or outside of the mouth. The curette is quickly reintroduced and a supplementary sweep is made with it on each side to clear away any lateral fringe. An examination is now made with the finger to ascertain if the removal has been complete, if so, the tonsils are quickly removed, unless from their size it was necessary to remove them before the adenoids, and the child is turned well over on to his side to allow the free escape of blood through the mouth. This might be termed the normal operation and its success depends chiefly on the proper engagement of the adenoids. If the curette is not kept well up to the septum an anterior fringe is very apt to be left, whilst if the curette is too small crushed lateral pieces are left which may escape the supplementary lateral curettement. I use a No. 3 size Gottstein for all small children and larger sizes for the older and bigger ones. The *tour de main* is largely a matter of practice, but when once acquired it can be accomplished with exactness and celerity. If examination with the finger shows that removal is not complete the curette must be used again or a small pair of Jurac's or StClair Thomson's forceps may be substituted. A small-sized Hartmann's curette is often useful to clear lateral processes from Rosenmüller's fossæ and Meyer's ring knife is the most efficacious for clearing fringes extending into the inverted V-shaped nostrils. The examination by the finger should always include the posterior nares and the condition of the posterior ends of the lower turbinateds should be noted. If they are much hypertrophied, which is seldom the case in children, it may be advisable to deal with them at once by snare or otherwise according to the condition.

The risks of the operation, apart from a fatality at the time which I have already dealt with, are slight. Hæmorrhage is sometimes profuse, especially if the lateral plexus of pharyngeal veins is wounded, or the mucous membrane torn away, but it rapidly ceases after the operation is finished. Recurrent hæmorrhage is very rare. I have only had one case and that was in a hæmophilic patient who had not thought it worth while to mention the fact. Secondary hæmorrhage, too, is as rare. I have only had one case, in a child, aged six years. This occurred on the fifth day after removal of the tonsils and the adenoids and was very severe, a large quantity of blood being lost. I saw the child the day afterwards with Dr. G. St. Johnston and found that the bleeding had not come from the tonsils. Chloride of calcium was given, rest in bed and suitable diet were ordered, and no further bleeding took place. Sepsis is another danger, but should not occur if proper septic precautions are taken as pointed out in the last lecture when speaking of tonsillotomy. Earache culminating in some cases in acute otitis media may be due to sepsis, injury to the tubal orifice, exposure to cold, imperfect removal of the adenoids, and injudicious syringing and irrigation after operation. A slight febrile condition lasting for 10 days or longer is generally caused by inflammation of remnants of adenoids or laceration of the mucous membrane.

At the conclusion of the operation the patient should be at once removed to bed, the head and shoulders being raised, and encouraged to sleep. The parents or friends—if a nurse is not in charge—should be warned that some blood swallowed at the time of operation will be vomited or they may be much alarmed. Cool or lukewarm fluids only should be given on the first day and soft milk foods on the two days following, the patient remaining in bed for this time. An aperient should be given if necessary on the second day. If on the fourth day the temperature is normal the patient may be allowed up but should be kept quiet in an even temperature and on light diet for a full week from the date of operation.

The degree of pain experienced after operation is very variable. For the first few hours there is a good deal of soreness and pain, often referred to the ears and not to be confounded with earache, and some headache. If this is severe a few doses of phenacetin will give relief. Subsequently pain is only felt on movements of deglutition and is but slight after the third day. No local after treatment is necessary or advisable unless febrile symptoms develop or if the naso-pharynx and nose are stuffy and the breath is offensive. Then a cleansing alkaline wash (borax, three grains to one ounce) may be gently sniffed or syringed through the least free nostril and a powder of aristol and boric acid insufflated. If there is earache gentle inflation of the middle ears with a Politzer air bag after the cleansing will give relief and may prevent further mischief.

Should sepsis by any chance occur more vigorous treatment will be required. Cleansing antiseptic washes or spray must be frequently used and followed by insufflations of aristol into the naso-pharynx. A look-out must be kept for septic pneumonia or other complications and suitable constitutional treatment must be employed.

When the patient is convalescent nose-breathing exercises should be carried out for a time to hasten the restoration of this function in those cases where it has been in abeyance. If there has been previous middle-ear trouble regular inflation with Politzer's air bag is generally advisable for so long as any improvement is obtained by its use. A course of iodide of iron is often of much benefit and a few weeks at the seaside is most desirable if it can be managed.

Disappointing results after operation occasionally happen but if a careful examination is made both before and at the time of operation the disappointment may be foreseen and the parents prepared for it. For instance, anterior nasal stenosis chronic otitis media, perforated and cicatricial membranes, &c., should be diagnosed at the prior examination and allowed for in the prognosis. A guarded prognosis, too should be given in all cases where the operation is undertaken for reflex symptoms. However probable it is that adenoids are the cause of the reflex in no case can it be said that their removal will effect a cure. Another source of disappointment is found in those cases where the symptoms prior to operation were in part due to a general catarrhal tumefaction of the mucous membrane. This will recur with each fresh cold and produce similar but perhaps not quite such intense symptoms. Atresia or arrested development of the posterior nares, a shallow naso-pharynx hypertrophy of the posterior ends of the lower turbinateds, projecting vertebræ, undue projection of the Eustachian prominences (which I have seen occupy quite half the space in the naso pharynx) will be found either before or at the time of operation and their bearing on the result should be explained.

A faulty operation is perhaps the most common cause of failure. If incomplete the persistence of the symptoms is attributed to recurrence—a great saving clause. If on the other hand, mucous membrane is torn away or stripped down patches of granulation tissue will form, and if extensive may become exuberant and simulate a recurrence. I well remember some 10 or 12 years ago reading in a medical journal (I cannot recall the reference) a report of three cases where in spite of a clearance *down to the periosteum* a recurrence had taken place. I felt no doubt that the recurrence was a mass of granulation tissue.

A more remote cause of non improvement of hearing is the occurrence of adhesions between the Eustachian prominence and posterior wall of the pharynx. In some cases I have found Rosenmüller's fossæ almost obliterated. The occasional voice defect from inability to approximate the palate to the posterior wall of the pharynx has already been referred to.

True recurrence is very rare. One can conceive of flat patches but little hypertrophied escaping the forceps or ring knife and subsequently enlarging but I fear that a faulty operation is the reason for most of them.

Of all operations complete removal of adenoids in suitable cases gives the most gratifying and successful results—results apparent to all brought in contact with the child—and it behoves us therefore to exercise every care to prevent disappointment by a careful examination beforehand and by a methodical and thorough operation.

THE Sheffield Watch Committee has decided to memorialise the Home Secretary, states last week's number of the *Local Government Chronicle*, to confer powers on some responsible authority to prohibit parachute performances.

THE RELATION OF VITAL STATISTICS TO SANITARY REFORM.[1]

BY ARTHUR NEWSHOLME, M.D., F.R.C.P. LOND.

THE subject on which I have been asked to address this Conference demands a definition of both vital statistics and sanitary reform. Sanitary reform is, I think, best defined by a statement of its objects, which are to enable man to reap the full harvest of his years of life and to diminish, and as far as possible to remove, the sicknesses and accidents occurring in the course of his life, thus improving its quality besides increasing its quantity and bringing about the realisation of the vision of the prophet Isaiah: "There shall be no more thence an infant of days, nor an old man that hath not filled his days; for the child shall die a hundred years old." Vital statistics are the collected and accurately presented facts concerning the human lives of communities. They deal with everything that concerns their welfare or has any bearing on the conditions of health or duration of life of their individual members.

The opinion has been expressed that our national system of vital statistics inaugurated in the first year of Queen Victoria's reign has been the active cause of all the sanitary progress that has followed. Without agreeing with this to the full extent it is certain that the periodical publication of our annual death returns, tabulated according to locality and according to age, sex, and causes of death, has given an enormous impetus to the adoption of measures calculated to diminish sickness and has hastened the adoption of these measures.

HISTORY OF STATISTICS BEFORE NATIONAL REGISTRATION.

Our national history before the Registration Act of 1837 came into operation furnishes striking instances of its necessity. The first parish registers of deaths were kept in England in 1538, and the "Bills of Mortality" were published towards the end of the same century, in order to quiet public feeling by giving a correct account of the progress of the plague. The supposed cause of death was after a while inserted in the registers, but ages were not added until 1728. Hence when Dr. Halley was studying the probabilities of life at every age and preparing his paper[2] which laid the foundation of life assurance he found it necessary to utilise the statistics of Breslau in Silesia, that being then the only place in which a record of the ages of the dead was kept.

Dr. Price nearly a century later published a life table based on the experience of one parish forming nearly half the population of Nottingham during the years 1735-80, and this table was used by insurance societies as the basis on which they calculated the annual premiums payable by insured persons and by the Government in calculating annuities. It was subsequently found that, there being a large number of Baptists in Nottingham, the church registers were very deficient and that the average lifetime in Nottingham was 30 and not 24 years as given in the table. The insurers in insurance societies were therefore paying premiums which were extravagantly high, while the Government was granting annuities at a rate which would speedily have rendered bankrupt any private business concern. Before the error was detected two millions sterling of the country's money had been lost on annuity transactions—a loss which might have been avoided had there been a national registration of births and deaths and a periodical census such as are now in operation. No better example of the risk incurred by substituting conjecture for inquiry could be adduced.

PARISH REGISTERS.

But although national registration was not established until 1837, records of local mortality in the parish registers, possibly not complete, had been previously utilised by medical and sanitary investigators. Thus in Manchester the death rate in the middle of the eighteenth century was stated to be 1 in 25, in 1770 it had become 1 in 28, and in 1811 had fallen, if the records be trustworthy, to 1 in 74, while in Liverpool in the same year it was 1 in 30 and in Birmingham

[2] Philosophical Transactions, No. 196, year 1693.

1 in 34 of the population.[3] Contrast these figures with the more recent, though still unfavourable, experience of Manchester. In 1841–50 and again in 1861–70 its death-rate was 1 in 30; in 1899 it had fallen to 1 in 42.

CHOLERA AS A SANITARY REFORMER.

The most potent influence in support of the efforts of the early sanitary reformers was cholera. So far from being an unmixed evil in this country cholera may not improperly be regarded as *facile princeps* as a motive power towards sanitary reform. In 1831–32 this disease caused 41,544 deaths in Great Britain and Ireland; and it is not surprising that local boards of health were during 1831 formed voluntarily in many parts of the country and that spasmodic, though very imperfect, efforts were made to sweep the Augean stables of insalubriousness. In connexion with these efforts the necessity for a complete registration of deaths became more evident and happily a political movement among Nonconformists hastened its adoption. Nonconformists were agitating in favour of a law that should enable the births, marriages, and deaths of all persons in the United Kingdom to be duly registered by the State and not exclusively by the Church as established by law.

NATIONAL REGISTRATION AND ITS EFFECTS.

The office of Registrar-General of Births, Deaths, and Marriages in England was created in 1836. The first report of the Registrar-General was published in 1839, and to this report Dr. W. Farr contributed the first of that long series of essays which have been the basis of the science of vital statistics in this country. In these reports the mortality of every district throughout the country has been the subject of analysis. The attention of local authorities has been compelled to any special incidence of deaths in their districts. Medical officers of health have been created throughout the country, one of whose chief duties is to draw forcible attention to the local incidence of deaths and to recommend measures tending to decrease the sickness and death-rate. Where the local supervision has been lax or the medical officer's recommendations have not been carried out the Registrar-General's periodical returns have enabled the medical staff of the Local Government Board to intervene and to investigate any local outbreak of fatal disease. The publicity given to the Registrar-General's weekly, quarterly, and annual reports has evoked a spirit of inquisitiveness and even of emulation throughout the country; and although the comparison of death-rates of great towns with each other, particularly for short periods, is fraught with fallacies the general result of the publicity secured and of the consequent efforts on the part of local authorities has been an immense improvement in the public health of the community. It cannot, for instance, be without effect in stimulating the City Council of Manchester to greater efforts that the future life-time of males in the community under its control based on the experience of 1881–90 was 28·8 years in the township and 34·7 years in the whole city, as compared with 40·7 years in London and 43·6 years in Brighton. Such an important statement would be impossible without accurate data as to both deaths and population Nor can it be uninstructive that the mortality of textile workers at ages between 25 and 65 years is 11 per cent. higher than that for all occupied males; that such workers "die more rapidly than do occupied males generally" from rheumatic fever, from diseases of the nervous and respiratory systems, and from affections of the digestive organs other than the liver; there being an excess also under the heads of consumption and heart disease; and that, furthermore, at ages over 35 years the death rates of Lancashire cotton operatives are higher than those of cotton operatives in the aggregate.[4]

These instructive examples might be multiplied indefinitely. While guiding us into the channels in which the greatest scope for, and possibilities of, improvement exist our vital statistics furnish us with encouragement in view of what has been already achieved. Nothing can be more gratifying than the disappearance, under conditions of diminished overcrowding and increased domestic cleanliness, of typhus fever from our national death-returns in all parts of the country except in a few corners of Lancashire and very rarely in London. Our statistics also show how typhoid fever has steadily declined in districts in which a complete water-carriage system of removal of excrement has been adopted; how it is more prevalent where pail closets than where water-closets are in use; and much more prevalent still where privies and privy-middens remain, notwithstanding our accumulated experience in condemnation of them.

The series of reports issued from the Registrar-General's office during his tenure of office from 1838–80 by Dr. Farr are not only classical contributions to vital statistics but have had an immense influence in promoting the public health; while the later reports by his successors, Dr. W. Ogle and Dr. Tatham, formerly medical officer of health of Manchester, are of even greater importance in view of the increasing accuracy of our national records of causes of death. As eloquently said by the late Sir B. W. Richardson, speaking of Dr. Farr's reports, it is now no longer true that pestilence walketh in the dark. It is measured and registered, walketh at last in the open day.

FALLACIES OF FIGURES.

That numerical tests of progress and numerical comparisons of experience are beset with fallacies scarcely needs emphasising. There are no witnesses more pliable than figures and they are frequently misused. The results of experience cannot, however, be stated except on an actual or implied numerical basis; and statistics merely present the collected experience of a number of persons. If inaccurately collected, if used in a manner which breaks elementary rules of arithmetic or logic, the fault lies not with the statistics but with their manipulator; and the remedy lies not in the disuse but in the corrected and extended use of accurate statistics.

INSUFFICIENCY OF DEATH REGISTRATION AS THE BASIS OF PREVENTIVE ACTION.

Experience soon showed that registration of deaths gave a very imperfect view of the prevalence of disease and that so far as communicable diseases were concerned invaluable time was lost when preventive action could only be taken after the registration of the patient's death. Preventable diseases from the viewpoint of administrative public control need to be divided into three groups: (1) those in which the chief danger lies in contact between the sick and the healthy—e.g., small-pox, measles, whooping-cough, scarlet fever, and diphtheria; (2) those in which, although contact between the sick and the healthy is the chief danger, this danger arises particularly under conditions of overcrowding, dirtiness, and general neglect—e.g., typhus fever, typhoid fever, and consumption; and (3) those in which the removal of nuisances and allied conditions, and particularly the prevention of the admission of excremental and other putrefiable matters to food, will diminish, and may even annihilate, disease—e.g., typhoid fever and diarrhœa. For diseases under the first heading our only present hope, with the happy exception of small-pox, lies in early knowledge of every case and every suspected case and the immediate institution of measures of isolation, disinfection, &c. For diseases under the second heading early prevention of the spread of their specific contagia is equally necessary, but along with this the opening out of insanitary areas, the removal of back-to-back houses or their conversion into through houses, the rigid enforcement of efficient building by-laws, the prevention of overcrowding, and the promotion of a high standard of domestic cleanliness are equally important. For diseases under the third heading the municipal supply of pure water has done wonders in the absence of notification of cases, though the latter is a valuable means towards the execution of further measures. A pure milk-supply, the forbiddance of the sale of shell-fish from sewage polluted estuaries, and allied measures are capable of effecting a still greater amount of good. In regard to all the above groups of diseases notification of all cases to the medical officer of health is the finger-post which indicates the places where sanitary investigation and action are peremptorily required.

VOLUNTARY SYSTEMS OF NOTIFICATION.

The association in connexion with which this meeting is held can claim to have been one of the earliest to organise a voluntary system of notification of various kinds of sickness and to have, unlike other districts in which similar attempts were made, carried this out successfully for a considerable number of years. This organisation I have described elsewhere[5]; it has also doubtless been described in your proceedings by Dr. Arthur Ransome, its pioneer, as it is an important and epoch making section of the history of the Manchester and Salford Sanitary Association and I need not, therefore, give further details in this paper Like other unpaid voluntary systems it gradually failed from continued lack of support.

[5] A National System of Notification and Registration of Sickness, Journal of the Royal Statistical Society, vol. lix., Part 1.

Compulsory Notification of Infectious Diseases.

With the failure of voluntary notification the conclusion was gradually reached that the compulsory notification of infectious diseases was the most urgent branch of a national system of registration of diseases, and this came into operation in a characteristically British fashion. Between 1877 and 1887 a large number of enterprising local authorities applied for, and obtained, the necessary powers securing the compulsory notification of the more important infectious diseases In 1888 an important step forward was, under the leadership of Dr. Tatham, taken by the medical officers of health of 33 towns in which notification was then in force, an arrangement being made for a weekly exchange of returns of the notifiable diseases, thus enabling forecasts of, and preparations against, the importation of disease to be made. In 1889 the Local Government Board was induced to take over this work and this body now sends out week by week a statement of the number of infectious cases in 225 towns and districts as well as in the metropolis. In 1899 the notification of the chief infectious diseases became compulsory throughout England and Wales, and we have therefore "in the making" invaluable statistics on which it will be possible to build great extensions of our knowledge of the natural history of these diseases. This, although not the immediate object of notification, is not to be neglected. When a disease belongs to the third group previously described this wider view may with relative freedom from loss be ignored. When, however, we come to deal with the members of the first group, diseases like diphtheria, which at long intervals become widely epidemic and then die down, and diseases which, like scarlet fever, vary greatly in their natural virulence, it is only by investigations of epidemics and pandemics on a large scale that we can hope completely to unravel the tangle of conditions which determine their prevalence. Medical officers of health are not mere empiricists concerned with the enforcement of general cleanliness and of disinfection and isolation when cases of infectious disease *arise. They are concerned not* solely with individual cases of disease but also with the conditions producing and controlling entire epidemics. It is in this branch of their work that knowledge is as yet most imperfect, and it is largely by the accumulation of accurate and complete information as to each epidemic and inter-epidemic period, and by the collateral study of the personal and environmental conditions associated with these periods, that we hope to arrive at a less empirical and more rational conception of the causation of each infectious disease and thence of its *prevention.*

It is not necessary to argue before the present audience the desirability of the notification of infectious diseases. Obviously notification cannot cause any extension of these diseases and if, as already indicated, it increases our knowledge of their natural history, it may lead to conclusions of the widest utility Furthermore, if preventive measures, whether in the removal of insanitary conditions or in the isolation of the sick, are enforced as the result of notification the prevalence of the notified disease must be to that extent diminished.

Notification of Suspected Cases—

If notification has not accomplished all that was expected of it it is because (1) the known measures of prevention which should have followed on notification have either been neglected or been perfunctorily carried out, (2) many cases have escaped notification; and (3) frequently diagnosis is delayed and infection is spread before isolation is begun.

The failure to notify a few slight cases of diphtheria may prolong and extend an epidemic, although every precautionary measure is being taken in connexion with notified cases. Cases furthermore are often notified after being watched for several days, with the natural result that secondary and tertiary cases are common in the same household The law in this respect is much more regardful of the welfare of cattle than of human beings. A medical man need not notify a case of scarlet fever until "he becomes aware" that it is certainly of this nature, a farmer must notify each case *and each suspected case* of foot and mouth disease or glanders A parent need not call in a medical man for every suspected case, and if he does not he can rarely be proved to have wilfully failed to inform the medical officer of health of an infectious case, as the proof involves the assumption that he or she possesses medical knowledge; and in the absence of such proof the parent cannot be punished for keeping the case secret. This may be said to be an argument against notification, it is rather an argument for improving its machinery Imperfect information must be better than no information

—And Free Medical Diagnosis for School Children Advocated

The time is ripe, I think, for asking for the compulsory notification of all cases in which there is reasonable ground for suspecting the existence of an infectious disease. As matters now stand children continue to attend school from a house in which a patient is suffering from "ulcerated throat," a "swab" from which might have sufficed to prove that it was really diphtheria, and so similarly for other diseases. The prevention of disease can never be effective and complete until such cases are brought to the attention of the medical officer of health and until precautionary measures are required to be carried out as soon as suspicion is aroused and before the certain diagnosis of the character of the illness The difficulty is much greater when no medical man is in attendance. An attack of diphtheria or scarlet fever may be so slight as to cause little inconvenience Why, then, should the parent call in medical aid? At the meeting of the British Medical Association at Portsmouth I advocated a system of free medical visitation of school children for purposes of diagnosis. Such a system would remove the parent's excuse for not calling in medical aid. It would, by securing in an increased proportion of cases early diagnosis, diminish the prevalence of infectious diseases and the diminished expenditure on maintenance of patients in isolation hospitals would probably more than recoup the fees of the medical practitioners who in their capacity as municipal officers had been called in to make a diagnosis. The insistence on a preliminary tentative notification of suspected cases of infectious disease and the provision of a gratuitous medical visit to children of the poor for diagnostic purposes are not the only necessary reforms.

Extension of Schedule of Notifiable Diseases.

The schedule of notifiable diseases requires extension In other words, we should revert to something nearer the original scheme of the Manchester and Salford Sanitary Association, the arrangements to be made for this extended notification being modified *so that weekly returns* may be obtained of diseases concerning which immediate information is not so urgent. Here again progress is being made according to the British fashion. Your medical officer of health, Dr J Niven has been a pioneer in the advocacy of measures against consumption and you have in operation a system of voluntary notification of cases of this disease In Brighton voluntary notification of consumption was inaugurated in January, 1899, and its operation has been practically free from friction and attended by good to an extent which is only limited by the number of notifications. Many other towns are following these examples and there is already advocacy of compulsory notification of this *disease.* My personal opinion is that the time is almost ripe for compulsory notification of changes of address of patients suffering from consumption, the compulsion only coming into operation when the medical attendant is unable to certify that there have been no recent infectious discharges rendering disinfection and cleansing necessary before the vacated rooms are occupied by a new tenant On the desirability of the notification of pneumonia and rheumatic fever it is not necessary that I should dilate The notification of certain industrial diseases is already an established and important fact.

Assistant Medical Officers of Health Required

The more extensive becomes our knowledge of communicable and other preventable diseases the more evident it is that much greater use will need to be made of skilled medical investigators. *There is risk in connexion* with the present stress of routine work falling to the lot of the medical officer of health of a large town that he may become and remain merely a bureaucratic administrator In Manchester a good example *has been set by the appointment* of one assistant medical officer of health. Probably others will be required and other towns will need to follow your example. The gain in removal of the intimate causes of disease in diminution of suffering and in financial strain on the funds of the Poor-law administration and of our voluntary and municipal hospitals will amply recoup the expenditure involved.

I have necessarily in this brief sketch of my subject omitted many questions of importance. Nor can I more than allude to the importance of securing periodical returns from friendly societies and other sickness assurance societies to the medical officer of health; to the desirability of transference of the statistical work in connexion with notification from the Local Government Board to the General Register Office. Certain steps in this direction have been already taken at the suggestion of the Incorporated Society of Medical Officers of Health.

The science of medicine, including preventive medicine, makes no idle promise to extend human life beyond its natural complete term. It will—if the proper means to this end, some of them enumerated in my preceding remarks, are supplied—conduct all who live in accordance with the principles of preventive medicine in safety to the natural boundaries of their present being; it will enable them to escape the risks of early and middle life and to ensure that their

"Age is as the lusty winter,
Frosty, but kindly."

To enable it to achieve this end not only is it necessary to improve the sanitary conditions of life in our cities from the standpoint of home, occupation, and municipal control, it is also necessary that every information capable of helping him in his work shall be given to the medical officer of health and his staff. He cannot make bricks without straw, he cannot forge his chain of preventive measures when half the links are missing. Possessed of this information and having secured the coöperation of an educated public he will be able to secure the maximum duration and the highest quality of life for every member of the community whose interests he guards.

Brighton.

EMBRYOLOGICAL ASPECTS AND ETIOLOGY OF CARCINOMA.

BY J. BEARD, D.Sc. VICT.,
UNIVERSITY LECTURER IN COMPARATIVE EMBRYOLOGY, EDINBURGH.

AT a time when so much is being attempted in the investigation of the problem of the nature of cancer it may appear presumptuous on the part of an embryologist to express opinions and conclusions regarding this grave question. It has long been a subject of earnest research by physicians and pathologists who naturally are thoroughly familiar with actual facts and finds concerning carcinoma foreign to the embryologist. But hitherto the physician and the surgeon, the pathologist and the gynæcologist, have utterly failed to establish anything concerning the etiology of cancer, and without the intervention of the embryologist success may be as distant in the future as in the past.

As indicated by the above title, the present writing is intended to deal with aspects of carcinoma as they strike an embryologist, and not every embryologist but one particular investigator. At the outset it may be asked, "Is the etiology of carcinoma an embryological problem?" As the thing itself and its manifestations demonstrably fall within the province of the surgeon and the pathologist, for it confronts them almost daily, it is possibly not very clear why the problem of the nature of cancer should be an embryological one at all. It is a disease carrying with it death and destruction. On the other hand, the problems of the embryologist, as generally understood, treat not of disease but of the blossoming forth of life itself, of the phenomena which culminate in the appearance of new living beings. Death and decay would seem to be things of which from his researches the embryologist might be expected to obtain no practical knowledge. He is supposed to be concerned with "das Werden," while "das Vergehen" is beyond the scope of his researches. Would that it were so! Unless he shut his eyes to plain facts "das Vergehen" in the midst of "das Werden"—death in budding life itself—is continually before him.

The conviction, impressed upon the writer's mind from 14 years devoted to the study of the mode of the development of the higher animals, the vertebrata, is that everywhere and at any point atrophy and death may be met with in any individual life-history. Death and degeneration of cells, of organs, of organisms, of embryos themselves, are among the commonest phenomena under the eyes of the embryologist. His text-books, even his published researches, may be silent of these, for as a rule he believes himself to be solely concerned with the coming-into-being, and the opposite aspect, the decline of life, he leaves severely alone. It is not in his tacit opinion a theme of the science of embryology. This view of the problems of the science has for many years failed to commend itself to the writer and in his own researches he has endeavoured to take account of everything happening and capable of being observed during the developmental cycle, whether progressive or retrogressive.

The manifestations of life present themselves under the headings of either form and structure or function. Embryological research deals largely with form and structure or, more exactly, with the coming-about of these. And as, according to the testimony of pathologists, cancer, when it appears, is something new to the organism, a neoplasm, a foreign thing, not growing and functioning after the manner of the individual containing it, increasing by cell-division after unknown laws which appear to defy all law, carrying with it widespread destruction only comparable to that dealt out by some parasites, the phenomena of cancer would have analogies at least to many such lying within the domain of the embryologist. Cancer is something with a beginning, it increases like a developing embryonic germ by cell-division, it invades territory at first foreign to it, and it only differs from a parasitic organism in the fact that its mode of reproduction is what may be defined as asexual. And thus, because as a rule its cycle is limited to the individual harbouring it, carcinoma is something with for itself an indefinite life-cycle which is only bounded by the life of its host but which cannot be directly carried over by germs or fertilized gametes to another organism.[1] That the resemblance between the life-cycle of a cancer and that of a metazoan organism should be incomplete is natural, for the former is an abnormal product and it is in the nature of such to differ in some or other important details from the typical or normal.

The problem of the nature of cancer has long been before the writer in his investigations—in fact, ever since he learnt from the researches of Wilms[2] and others that it had been occasionally encountered along with those curious tumours, the dermoid cysts of ovary or testis, the "embryomas" or rudimentary embryos of Wilms. The latter speaks of this occasional connexion of the two—it has, according to Wilms, been observed some nine times—as a remarkable fact (p. 86) in that in an organism of one or two years of age the development of carcinoma can happen. As this relates to the presumed age of the embryoma and not to that of the individual harbouring the latter, the validity of the conclusion is not apparent. On his part the writer must reject it. For the past two years from time to time in researches upon the germ-cells observations have been made[3] which appeared to have bearings upon the nature of carcinoma. This period may not seem a long one, but beyond it lie the investigations of other 12 years, without which the standpoint of to-day would be an impossibility. If, therefore, no study of cancers underlies the present writing, the approach of the problem is not a sudden one, but it has been preceded by prolonged observation and, moreover, animal life is the same, whether it be that of a hydroid polype upon a shell of the sea-shore or that of a cancer within an individual of the human race.

The immediate cause of the present writing was as follows. In a recent paper dealing with the understudy theory of heredity in an altogether different connexion a few comments have been written upon the mode of growth exhibited by certain organisms and a comparison drawn between this and the pernicious growth of the human chorion in certain cases.[4]

---

[1] It has, however, been shown by Hanau and Wehr to be possible to transplant cancer from one individual—e g., the dog—to another.

[3] Ibid.

[4] The passage in question is as follows: "It should be mentioned that de Vries and Weismann have already noted the resemblance in mode of growth between the sporophyte and the colonial hydrozoa. Many of the latter also possess the indefinite unrestricted power of growth so characteristic of the sporophyte of the higher plants. As a rule, the asexual generations of the higher metazoa do not exhibit this faculty. They rarely obtain a chance of showing it, for it is their usual fate to undergo early suppression by the sexual generation.

And it was not until long after the proof had been returned that it was seen how in this comparison the key to the problem of the nature of cancer had been given away. If the pernicious growth of the chorion be in reality carcinomatous, and it is recognised[5] as such by pathologists under the *names of malignant placentoma, deciduoma, chorion-epithelioma*, or destructive placental polype,[6] the cause of cancer is clear as the light of day. And it has seemed desirable to offer the present essay in order that at least a warning note might thereby be uttered and an earnest attempt made to point to the futility of investigation in the direction of a cul-de-sac, such as the probable one of cancer as due to unicellular *organisms*. In the *following* the facts concerning carcinoma, as established by pathological research, such as those given in the latest edition of Ziegler's "Pathologie," will be taken for granted. It will be assumed that at the basis there is morphologically but one form of cancer, no matter how different it may appear to be in diverse localities. A cancer of the skin is naturally different from one of the stomach or liver, for it grows and increases under other conditions. Ziegler for one adduces reasons against the supposed origin of cancer from some effects of unicellular organisms, and to his objections something more can be added. It is not in the nature of parasitic maladies to lead to cellular increase, such as is characteristic of cancer, and while the phenomena of destruction possibly present themselves prominently to the surgeon and the pathologist, those of indefinite unrestricted cellular increase and multiplication most impress the embryologist. And if the source of cancer to be brought out in the course of the following be the true one any further cause is a superfluity.

The conclusions are based chiefly, but not entirely, upon researches in elasmobranch fishes[7] and to any but vertebrate embryologists there might appear to be no warrant for applying results obtained in animals so low down in the scale to man himself. But the broad outlines, the laws, and even most of the details of the development are the same in man as in the fishes, and the life-cycle of the former can be interpreted in terms of that of the latter. The starting-point goes back more than two years to the beginning of researches upon the germ-cells, and with these to the earlier work of Wilms upon the embryomas. The results of the work and of previous necessary inquiries dating as long ago as 1889 *cannot be given at all in detail here*. A general survey of the chief conclusions will be found in "Heredity and the Epicycle of the Germ-cells."[8] The cause of cancer is really known but not recognised. Failure to perceive the true nature of carcinoma has hitherto been due to one simple fact: the views generally, nay universally, held and taught regarding the course of the cycle of development from egg to egg are erroneous.

Were an embryologist of to-day asked what in outline was the cycle of development in one of the higher forms, say a fish, chick, or mammal, he would probably be amazed at the question. "The hen lays the egg, the latter gives birth to a new hen," and so, as Kleinenberg once remarked of something else, under the eyes of the delighted and astonished spectator the cycle is completed. This supposed cycle has never really been witnessed—for the very good reason that it does not exist. The hen neither produces the egg nor is it the chief nor even the immediate task of the latter to give rise to a new hen. As the establishment of this and of the true life-cycle have filled in the working hours of the writer during more than a dozen years it may be obvious that the production of the evidences must be beyond the limits of this short paper. At the moment a pretty big book would be required to hold them all. Indeed, no attempt will be made to prove here what the true life-cycle is and wherein its details lie; the results of previous work will be assumed and for fuller information the reader may be referred to the series of memoirs whose titles are appended.

In the higher animals, the metazoa, what is termed direct development does not, and cannot, exist. It has been found that the cycle of animal development, even of the highest forms, resembles very closely that of a fern or flowering-plant. In the line from egg to egg there are two generations, an asexual form and one which, as it is the bearer of the sexual organs, is spoken of as the sexual generation. Under prevailing views of development the line of ancestry from generation to generation is exceedingly simple—too simple, indeed, to explain the facts, so simple that Nature could not adopt it in practice were she to make the trial. It may be represented thus: egg—*embryo or sexual generation*—egg—embryo, &c., the egg producing the embryo, the latter when mature forming from its own tissues new eggs. This is undoubtedly one of the most impossible conceptions which ever formed part of a science. The amended cycle of development and the course of heredity are as follows: egg—larva (phorozoon, or bearing animal, or asexual generation)—primitive germ-cell—primary germ-cells—secondary germ-cells—gametes, eggs, or sperms—fertilised egg. In the line of ancestry as given here—a line which apart from the larva is one of unicellular organisms—the embryo finds no place. It arises from one of the primary germ-cells whose number is always a definite one—2, 4, 8, 16, 32, &c.—and the rest enter the embryonic body to form its sexual products. A more detailed account of this cycle will be found in the memoir upon "Heredity and the Epicycle of the Germ-cells." The four important items in the cycle are: (1) the gametes, egg and sperm, by whose union a new cycle is initiated; (2) the first product of the zygote, the phorozoon, larva, or asexual generation; (3) the primary germ-cells destined for future generations; and (4)—only important to enable the completion of the cycle—the embryo or sexual generation

Any and every primary germ-cell, if it develop or unfold as such, normally gives birth to an embryo, and, as elsewhere indicated, the embryomas of Wilms arise, and must do so, from persistent primary germ-cells. This unfolding of a primary germ-cell is equivalent to its landing in a cul-de-sac—its powers of growth and increase and its life are thereby limited. The contrast between this and the larva or phorozoon in these respects is very striking. The latter, like the corresponding generation in plants, often possesses indefinite unrestricted powers of growth in an apical fashion.[9] *In many animals there is only one apical region* of growth in the larva; in the hydroid polypes there may be many such and Weismann and de Vries have already noted their powers of indefinite unrestricted growth. That which brings to a sharp and sudden close the growth of the phorozoon or larva, if there be but one growing point, is the cutting-off of this from the organism, its conversion into a primitive germ-cell, and the consequent formation of primary germ-cells from this. Normally, as already stated, the further development of a primary germ cell results in an embryo, not in a larva

Coming now to the primary germ-cells, upon which most of the observations of the past two years have been made, it has elsewhere been established that their number is always a member of the geometrical series: 2, 4, 8, 16, 32, &c., or 2 to the "n"th power, where "n" is one of the numerals 1, 2, 3, 4, 5, 6, &c., and that the greatest number of primary germ-cells in any embryo will be $2^n - 1$. Thus, the total number in the common dog fish, scyllium canicula, is 128, in the male smooth skate, raja batis, 256, in the female 512, and the greatest number *in the embryo of one of these* 127 (in scyllium), 255 (in the male skate), and 511 (in the female skate). But for convenience and brevity, dealing with one

---

When, as happens sometimes in cases of abortion in the human subject, the embryo is got rid of prior to the critical period, or, at any rate, before the asexual generation has here been suppressed, the latter may go on growing indefinitely if left in the uterus. I refer, of course to the unrestricted and pernicious growth of the chorion when left in the womb after an abortion." (Transactions of the Botanical Society of Edinburgh, 1902, p. 140-141.)

[5] The carcinomatous character of the pernicious growth of the chorion was first clearly recognised by Professor Marchand in 1895.

[9] Of great but hitherto unrecognised importance in this direction are certain results of experimental embryology, such as those of Driesch, Morgan, and others upon echinoderms and of E. B. Wilson and others upon amphioxus, &c. (For a full account see E. B. Wilson's "The Cell," second edition, 1900, or Korschelt und Heider, "Lehrbuch der vergleichende Entwicklungsgeschichte, Allgemeiner Theil, Jena, Gustav Fischer, 1902.) Space does not permit of a description and discussion of these experiments. The general result is that *in certain* animals, if the cells of the early cleavage of the egg be separated, each of them will give rise to a diminutive larva, the size of this varying directly with the size of the original blastomere. These minute larvæ are often but erroneously spoken of as "embryos." Though they may go on living for a considerable time no case *is known in* which an embryo with sexual organs arises upon such a larva, as, of course, would happen *in* a normal development. Allied to this latter circumstance is the fact that the invertebrate larvæ obtained by embryologists by artificial fecundation never give rise to the sexual form, no matter how long they may be kept living in the laboratory. The writer has reared echinoderm-larvæ for 15 days without the formation of a sea-urchin upon any one of them. Many other similar facts could be mentioned.

form only, say, the dog-fish (pristiurus), of the 127 primary germ-cells it never happens that all, or anything like all, reach the normal position, the germinal ridge, or nidus. Usually at the most from 90 to 100 of them arrive here, the remainder being found in all sorts of unusual places, where many of them degenerate.

The number of elasmobranch embryos hitherto examined is several hundreds, belonging to different species, and in all these under a certain age no single embryo has been seen in which all the germ-cells present might be described as normally placed. The percentage of vagrant germ-cells varies; it is usually from 10 to 12 per cent. in pristiurus and from 25 to 30 per cent. in raja batis. The places where these occur are numerous, in the body-cavity, upon the somatopleure, on the subintestinal vein, in kidney-tubules, in the pericardium, in the liver, in any part of the gut-epithelium, especially in the rectum, in the skin, rarely in the head or gill-region, and practically always there are some in the immediate neighbourhood of the stomach in connexion with the yelk-stalk. Undoubtedly many of these germ-cells degenerate and few, if any, of the vagrant ones, after a certain early period, ever find their way to the germinal nidus. The embryomas of Wilms are to be regarded as products of such vagrant or of persistent (in ovary or testis) primary germ-cells But—and this is remarkable—very many such vagrant germ-cells occur in places where embryomas are never encountered; thus in the immediate neighbourhood of the stomach, in the liver, in or under the skin, and in the rectum. In nearly every embryo one or more germ-cells may be found in the yelk-stalk in the immediate neighbourhood of the pylorus and also in the rectal epithelium.

It may therefore be suspected that if the germ-cells of many of these places—e.g., liver, pylorus, rectum, &c.—ever do develop they must give rise to some product not of the nature of an embryo, not an embryoma. It is not without interest that the common situations for the origin of cancer are the very ones in which vagrant germ-cells are usually met with—thus, in the rectum, near the pylorus (yelk-stalk), other parts of the gut, in the kidneys, in the skin, &c. Apparently cancer of the tongue, of the œsophagus, of the larynx, and of the mammary gland at the first glance form exceptions, but this is not really so. Tongue, œsophagus, and larynx are products in the higher forms of a metamorphosis of the gill-region; œsophagus and mammary glands are closely associated with the pericardium, where vagrant germ-cells (and sometimes embryomas as products of these) are often found. That cancer should arise in what embryologically are holes and corners, places where layers and folds come together, as in tongue and larynx, is readily explicable. Such vagrant germ-cells are intruders in the situations originally taken up by them, and it has often been remarked how they would appear to be hustled about from pillar to post when in the way until they land in some corner or other. Normally, if the paradox be allowable, the development of such a vagrant germ-cell should result in a more or less complete twin-embryo, but any gradation of this down to a very rudimentary embryo may be found in practice. Figured in Ziegler's "Pathologie" may be seen all sorts of steps, from complete identical twins, only abnormal in being united at some one point, through those more completely united, to others forming more or less complete embryos embedded within or projecting from a normal one, down to mere cysts or absolutely rudimentary embryos No one has ever witnessed the development of such a rudimentary embryo or embryoma, and probably it never will be seen, but the connexion between them and vagrant or persistent (in ovary or testis) primary germ-cells is not less certain than that between an onion and the seed originally planted. In the same way the hypothesis that the vagrant primary germ-cells of certain regions, thus those of the neighbourhood of the stomach and of the rectum if they develop, give rise not to an embryo, but to a larva of indefinite unrestricted powers of growth, can never be converted into a fact by direct observation. It can only be inferred from the facts But it is a very simple explanation of all the facts and its probability is increased by other considerations

But why should such a vagrant germ-cell, when developing into a cancer, omit or skip the formation of an embryo and proceed with a different portion of the life-cycle? One reason is, perhaps, clear. It is that the further growth of a vagrant germ-cell or of its progeny to form a cancer takes place at a much later period than that at which its embryological development into a more or less complete embryo should have happened. (The instances of cance with embryomas, noted by Wilms, do not form exceptions.) Moreover, it must not be forgotten that we are dealing with pathological conditions, with phenomena, which in some glaring way do not conform with the normal. Cancer is an attribute of later sexual life or of old age. For this reason one is inclined to suppose that it is not immediately due to the further development of a vagrant germ-cell itself, that this latter first of all divides many times, as it would do if in the germinal nidus, and that it ultimately forms more or less normal forerunners of gametes, oöcytes, or spermatocytes. These would be in abnormal situations and under abnormal conditions and under some stimulus they would develop as though parthenogenetically but abnormally to form a larva.

At the basis cancer is nothing more than the production abnormally of a phorozoon or larva within a sexual generation. Elsewhere analogues may be seen. In hermaphroditism we witness the conversion of the forerunners of male eggs (in what are really females) into sperms. In certain ferns abnormally upon the asexual generation or sporophyte what the botanists term "apogamy" is met with—i e., the appearance of a new sporophyte upon the original one—the formation of a sexual generation or gametophyte and of sexual organs being skipped. It has been urged from a botanical side that comparison between apogamy in certain ferns and carcinoma in a mammal would not be justified, because the former was an abnormal condition. But we are dealing with abnormalities and not with normal occurrences of the life-cycle If cancer be the abnormal production of a phorozoon or asexual generation by a vagrant germ-cell or its progeny, it may be asked why do not the other items of the life-cycle supervene? Why do not a primitive germ-cell, primary germ-cells, and embryo arise? Were this to happen the cycle, though commencing and being carried out under abnormal conditions, would revert to the normal, and from my experiences of abnormal development in various directions a reversion to the normal is always excluded. Were such an incipient carcinoma to form a primitive germ-cell, before the number of its apical or growing points had been increased, its portion of the cycle would thereby be brought to a close and it is in fact the omission of this which fosters and favours its indefinite unrestricted growth.

The etiology of carcinoma above suggested will be recognised as one whose nature indicates nothing favourable to its prevention or extermination. It may be said to explain completely its peculiarities and its hereditary character. But it is a despairing view. In this respect it is in only too close agreement with the experiences of physicians and surgeons. The one hopeful aspect is that in normal development at a certain period the embryo or sexual form is able in some way or other to suppress the asexual foundation upon which it arose and as a rule the victory of the former over the latter is complete.

As conceived here carcinoma would be a disease peculiar to mammals. For, as recognised by the writer some 10 years ago, in them the phorozoon or asexual generation has become parasitic in adaptation to uterine development. The possibility of carcinomatous development postulates uterine gestation at least for the normal life-span of the asexual generation—i.e., until what was termed the critical period. In fishes, such as the skate or dog-fish, neither a vagrant germ-cell nor its progeny could develop into a carcinoma, for the larval or asexual portion of the life-cycle is not passed as a parasite upon the parent (even in forms with apparent uterine development) but in sea-water; in other words, below the metatherian and eutherian mammals the phorozoon or larva is not adapted for a parasitic existence upon the parent organism and thus cannot become abnormally a parasite upon it. Carcinoma is not known below the mammals, the animal lowest in the scale in which it has been recorded being the short-headed phalanger, belideus breviceps.[10] This disease is a sequel to uterine gestation. If the cycle of metazoan development really be that concluded by the writer, if his interpretation of the phenomena of mammalian development—which are not in the least based upon facts or factors noted in cancer but upon normal development here,—if these be correct the cause of carcinoma is not hypothetical at all but is actually known. More than one cause cannot be assumed and if one cause be shown all other explanations become superfluous. In certain cases in human development, when either no embryo arises within the chorion or when the embryo becomes aborted or dies prior to the suppression of the phorozoon or larva, the latter, the chorion, may go on growing indefinitely and may give rise to what pathologists and gynæcologists recognise as a form of cancer, placentoma, or chorion-epithelioma (Marchand) For years now I have recognised—and in homologising this structure with the larval skin of an amphibian Hubrecht has gone a long way in the like direction—that the human chorion represents the main portion or whole of the asexual generation or phorozoon here. In certain cases therefore we here witness the conversion of the chorion—i e., of the asexual generation, or larva, into a malignant tumour, a carcinoma.

---

[10] J. Bland Sutton, Evolution and Disease, London, 1890, p. 247, Fig. 123. The case is one of cancer in the marsupial pouch.

What other proof could be asked for? That this proof of the nature of cancer is not in agreement with accepted views of normal development cannot be set down to the fault of the writer He holds, and has alone long maintained, such views to be false and unfounded in fact, and, moreover, it has been attempted to indicate the right way The arguments and conclusions have been neither refuted nor confirmed, but have been ignored. But embryologists are living, and have long been existing therein, in a mental universe, where but a tithe of the facts observed are explicable under their views. Under the conception of development as an antithetic alternation of generations, especially as laid down in "Heredity, and the Epicycle of the Germ-cells," all the known facts of development fit in, all are capable of easy and natural explanation And the elucidation of the etiology of carcinoma follows as a natural corollary to the law of the developmental cycle. The embryologist and the pathologist may ignore and neglect the plain and palpable fact, but on no theory of direct development—a thing only existing for the metazoan animals in the human imagination—can any explanation whatever of the nature of carcinoma be advanced. The cause of this would long ago have been clearly recognised had some embryologist taken the trouble, as the writer has done during 14 years past, to trace out in full the details of the life-cycle of one of the higher metazoa from egg to egg The idea of direct development, accepted without examination of the evidences, and the erroneous belief in the somatic origin of germ-cells have retarded the advance of knowledge to an extent difficult to estimate.

The nature of the argument employed in the present writing may be summarised as follows Granted the facts of the origin, migrations, and history of the germ cells of vertebrates, and assuming the course of the life-cycle to be that previously indicated, by hypothesis cancer is derived from vagrant primary germ-cells, which, instead of forming a more or less complete embryo or embryoma, skip this and give rise to a larva or phorozoon of indefinite unrestricted powers of growth. This is, of course, purely hypothetical, but it becomes the true explanation by the following facts On the one hand, as my researches have shown, the hypothetical "verirrte Keime" or "lost germs" of pathologists not only exist but they are numerously represented and by things capable of abnormal development, the vagrant primary germ-cells. On the other hand, the carcinomatous nature of such an abnormal growth of a larva or phorozoon has been abundantly demonstrated by Marchand for the instances of the pernicious growth of the chorion, chorion-epithelioma. If such a chorion the representative more or less complete of the asexual generation, when robbed of its embryo or when it fails to form such, can—and this is established—give origin to a malignant carcinomatous tumour the nature of cancer is clear The vagrant primary germ-cell is the seed, while its fruit, sometimes represented by an embryoma, may on occasion take the form of a carcinoma.

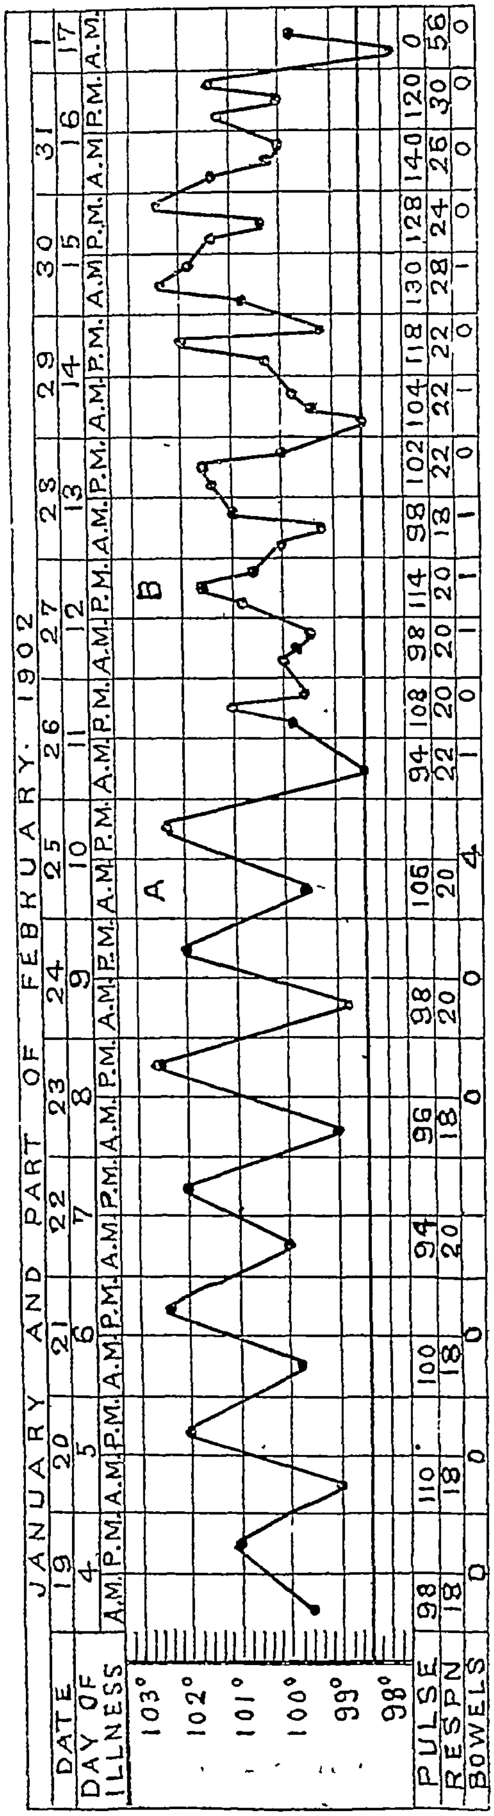
A CASE OF DIFFICULT DIAGNOSIS WITH A RARE COMPLICATION.

BY H. J MACKAY, M.D EDIN

THE patient was a married woman, 37 years of age, well-developed and healthy, of a sensitive, highly strung temperament, and with an excessive dread of pain and illness. No previous illness threw any light on the present attack. The family history was unimportant except as revealing the fact that two brothers and a cousin had died from enteric fever The illness started, it was supposed, with a chill, but of this there was no proof. On Jan 16th, 1902, having experienced for a day or two previously an ill-defined sense of malaise, she felt generally ill and was drowsy, shivery, and giddy Headache was present, as was nausea which went on to vomiting Cough, sore throat, and coryza were absent. After three days in this condition she sought advice and was seen for the first time on Jan. 19th the fourth day of actual illness. The symptoms already mentioned were then present and in addition she felt weak, faint, and depressed. She had gastric pain and felt sick She was constipated. The tongue showed a thin white fur which afterwards became thick, grey, and creamy The pulse was 96, regular, but weak. The temperature in the early afternoon was 99·6° F and it rose in the evening to 101°. She had slept badly Some cases of influenza of the gastro-intestinal type had occurred in the household about this time and it was thought that the patient was suffering from the same complaint. For the next five days the course of illness corresponded well with the diagnosis that had been made. The morning and evening temperatures from the fourth day to the tenth day, and a four hour chart from the tenth day to the sixteenth day, are appended. On Jan. 25th some tenderness in the right iliac region was complained of. It being now the tenth day of illness and the sixth of ascertained pyrexia the possibility of typhoid fever had to be entertained. A search for spots and splenic enlargement revealed nothing The bowels had acted on this day in response to a gentle aperient and four yellowish stools had been passed, but otherwise constipation had been the rule. All precautions were, however, taken and the patient was placed on enteric diet. An examination for Widal's reaction was clearly desirable at this stage but the patient shrank from the discomfort of the trifling puncture and in her weak state it was not insisted on On the 27th the twelfth day of illness, the diagnosis was still in doubt The onset, neither sudden nor insidious, had given no clear indication either way The facial expression showed impatience rather than apathy Hectic flush was absent. The pupils were of normal size. The tongue, though furred, was not parched Abdominal tenderness was trivial. Constipation was present and meteorism was absent. The heart sounds showed increasing weakness of the heart muscle The pulse, weak, occasionally irregular, of low tension, but not yet palpably dicrotic, varied from 96 in the morning to 120 in the evening At this date it was too early to suggest typhoid myocarditis the heart weakness fitted well with poisoning of the myocardium or of the vagus centre by the toxin of either disease. In other respects the patient on this day expressed herself as feeling much better and begged to be lifted for a few hours out of bed on to her couch. The wish was gratified to her great comfort and apparent benefit. At 7 30 P M while resting quietly, she was threatened with a sudden action of the bowels. In endeavouring to accommodate herself to the utensil she, forgetting previous warnings, actively co-operated with the nurse by raising her hips and trunk from the bed while in the dorsal position. She was immediately seized with abdominal pain, followed by pain in both legs from the middle of the thigh downwards. To this succeeded tingling in the legs and feet and soon afterwards numbness and coldness of the extremities. Examination shortly afterwards showed that the lower extremities were cold from the toes to the knees. The feet and the legs were pale. Pulsation was present in both femorals at the groin and in Scarpa's triangle, and the impulse was more forcible and larger than usual. Pulsation was absent in the popliteals, in the posterior tibials, and in the dorsales pedis. Anæsthesia to touch, pain, and temperature was present over the area involved. The legs were wrapped in warm alembroth gamgee, and while the gravity of the outlook was recognised it was hoped the arterial obstruction might not prove to be of a permanent nature. On the following day, however, the condition was unchanged, except for the ominous addition of purple mottling over both legs. Inspection of the trunk on this day—the thirteenth day of the illness—revealed four scattered roseolar papules two to three millimetres in diameter on the back and loins. Splenic enlargement could not be made out. The patient was seen in consultation at this time by Dr. J. Michell Clarke who was of opinion that embolism of the abdominal aorta had occurred and who agreed as to the difficulty of making a decided diagnosis as to the nature of the primary disease but considered the balance of evidence to be in favour of enteric fever. On the two following days—the fourteenth and fifteenth days of the illness—the abdominal symptoms became more pronounced. Peritonitic tenderness developed over the cæcum with some general tympanites. No further spots appeared. Frequent vomiting rendered nutrition difficult. On the 31st—the sixteenth day of the illness—at 4 A.M., a sudden drop of temperature from 101° to 97·6° occurred. Coldness of the hands and failure of the pulse at the wrist ensued. The patient sank and died at 11 A.M. A necropsy was not obtained.



A, Aperient. B, Out on couch from 4 to 7.30 P.M. embolic attack at 7.30 P.M.

Most authorities recognise the difficulty that may arise in endeavouring to distinguish between gastro-intestinal influenza and enteric fever. Watson,[1] Murchison,[2] Dreschfeld,[3] Goodhart,[4] Leichtenstern,[5] and Curschmann,[6] to name a few only, admit and discuss the difficulty. Goodhart affirms the occasional impossibility of distinguishing between the two diseases until some characteristic development occurs. The bacteriological test is, of course, the crucial one. But there are hypersensitive patients to whom even a needle puncture at the base of the nail is objectionable, and Pfeiffer's bacillus is not easily sought for in cases where no respiratory catarrh is present. In the case described diagnosis appeared possible only after the appearance on the thirteenth day of four roseolar spots. The subsequent lighting up of abdominal symptoms and the fatal drop in temperature on the sixteenth day appear to agree with the diagnosis of typhoid fever but do not confirm it. For apart from the fact that Dr. Michell Clarke is of opinion that these may have been due to thrombosis of the mesenteric artery, with subsequent necrosis of the bowel, there are none of the symptoms mentioned that would not fit equally well with the diagnosis of influenza.

Influenzal typhlitis and perityphlitis have been described by Teissier[7] and Leichtenstern.[8] Peritonitis "grippalis," so called, was a frequent complication in the pandemic of 1890 (Kelsch and Antony[9] and Leichtenstern[10]). Ulceration of the intestinal mucosa with hæmorrhage was noted by Mosler.[11] As regards the roseolar spots, Curschmann,[12] quoted by Leichtenstern, found a roseola present in 1·2 per cent. of the cases of influenza admitted into the Leipsic clinic. Whether this was an initial or a late rash is not stated. The late rashes, however (from the eighth to the fourteenth day), that have been described have been scarlatiniform, urticarial, erythematous, or herpetic. A roseolar, papular exanthem of a few spots only, resembling those of enteric fever and occurring during the second week, has not, so far as I am aware, been described as occurring in influenza.

The deplorable complication recorded above—viz., symmetrical blocking of both femoral arteries, is one of extreme rarity in this country, to judge from the scarcity of references to it in our medical literature other than that of quite recent date. The whole subject of typhoid gangrene, indeed, has that excrement would be sucked into the water-pipe. In January and February, when there were at least 27 cases of enteric fever in the town, closet-pans thus circumstanced were doubtless in some instances tainted with the specific contagium of enteric fever; some may even have been filled with excrement from the bowels of fever-patients. The sewer air which entered the pipes at night, when the water was turned off, would in the morning, when the water was turned on again, be driven forward, washing the pipe surfaces on which foul air had for hours been resting, and could hardly (even supposing no actual excrement to have got into the pipes) have failed to contain fever contagium; and this water went on, not only to cleanse closet-pans, but to be drunk by the people in the town. I think it probable that the recent outbreak of enteric fever was caused by persons drinking of this contaminated water and I base this opinion on the following considerations: first, the sudden appearance of so many cases in the first week in March—i.e., after the water had been shut off every night in February; secondly, by the gradual diminution of cases after the first week in March, during which month the water was not turned off at nights; thirdly, by the manner in which the cases were scattered about the town; lastly and mainly, by the fact that the proportion of cases occurring amongst persons who derived their water from the board of health supply was much greater than amongst persons who had their water from other sources" (Report of the medical officer of the Privy Council and the Local Government Board, New Series, No. II, for 1873).

In the same volume is a remarkable report by Dr. Buchanan on an outbreak which occurred in 1873 at Caius College, Cambridge, from which I extract the following: "All the more usual ways of enteric fever spread have now been considered and none of them have appeared adequate to account for the intensity of incidence of fever upon Caius College or for its remarkable incidence on Tree Court. Holding always in view the special character of these occurrences let us observe that the *water-supply* to the college is taken from a surrounding five-inch main at six different places, and that one of them, at the Gate of Humility, is for Tree Court and for no part but Tree Court. What if there should be something wrong with this one local supply? Even *primâ facie* there is something to be said for this view. The suddenness of the outbreak in the college was such as at once to suggest to Dr Paget and Dr Bradbury, and equally to myself, the thought 'that it might be due to the contamination of the water or milk.' The area of the particular water distribution is exactly the area of the fever, at least of 12 out of 15 cases, one or more of the remaining cases requiring probably no explanation beyond every-day circumstances. The good character of the company's general water-supply would not avail as an argument against a local contamination in a local service And at an early period of my investigation I was struck with the circumstance that while every water-closet in the old part of the building was provided with a cistern proper to itself, the closets in the Tree Court buildings were supplied with water direct from the high-pressure constant-service pipes Complete intermission of supply was found to have actually occurred on two occasions at least during the last term. The earlier occasion can be defined as the evening of the second day of an October frost, and thus far might have been either on Oct. 25th or on Oct. 30th, but other associations suggest Oct. 25th as being the more probable of the two days; on this occasion only the particular service through the Gate of Humility was stopped The latter occasion was when the water company's servants, having, for the purposes of pipe repair, cut off the water-supply of some half of Cambridge, there was hurrying to restore the supply in order to gain water-power to blow the organ of King's College Chapel for a musical service. This fixes the date of the second known intermission at about 10 30 A.M. on All Saints' day, Nov. 1st. Now a fortnight is about the incubation time of enteric fever. A fortnight after Oct. 25th is the date of the first attack in Tree Court. A fortnight after Nov. 1st is the date of the second, third, and fourth attacks. And though it was known that other cases of fever kept dropping in till the end of November the coincidence of the early fever with these ascertained intermissions was not the less suggestive as indicating the direction that further inquiry should take" Dr Buchanan then showed that the water in that main was contaminated by suction into it, during the periods of intermission of the supply, of foul air from a soil-pipe (and so from a sewer) through a "weeping pipe" which supplied the trap on the waste-pipe of th tray of a water-closet, which trap was liable to sink (Report of the medical officer of the Privy Coun the Local Government Board, New Series, No. II 1873.)

In the annual report of the medical officer of the Government Board for 1887 is an important report o epidemic of enteric fever in the Mountain Ash Urban tary District, Glamorganshire, by Mr. John Spear, in wh after discussing the evidence, Mr. Spear continues facts all tend to bring into more and more prominent re the point of *initial* contamination of the water, and, in vi of the now clearly established premises of my argument, t exact condition of the Oxford-street main and its relati to immediate surroundings become matters of exceedin interest and importance. I have shown that the water, a it passed into the main and for the first 160 yards of it course there, produced no ill-effects in its consumers; and have identified that point just at the Henry-street bifurcation as the one point indicated by the facts of fever prevalence where specific contamination of the water main had in all likelihood habitually occurred. For the purpose of this inquiry the two pipes were laid bare a little above and fo some distance below the point indicated. The Henry-stree pipe was laid some 25 years ago and has been found to be much corroded. That of Oxford-street was relaid, as I have said, in 1885. *There is no doubt that the relaying wa very carelessly, not to say recklessly, done.* Owing to the exigencies of water-supply it was done mostly at night, and the work being in private hands was subject to no supervision on the part of any official or authority having concern with the public health. Accordingly, the main was carried, without any special precaution, *immediately above, alongside, and even through the old rubble drains,* and when in the course of trenching pipe-drains were cut through no trouble appears to have been taken to replace them. I find the inspector of nuisances reporting in September, 1885, a third case of injury and stoppage of a drain from this cause. Although the old stone culverts to which I have referred are not ostensibly sewage-carriers now they formed the sole sewage system some 20 years ago; and even now refuse matters are often poured, as I saw myself into the roadside gullies that are connected with them. One of the culverts through which the Oxford-street main was carried (a 'collar' or junction between two pipes being in the interior was found to contain a quantity of excessively foul sewage deposit, a slaughter-house apparently, amongst other places, draining into it. It may be said that as one result of the careless laying of the main, the latter was at different points from time to time bathed in refuse matters and habitually at certain points in sewage-contaminated air."

Leakages were found in the mains and also direct con nexions with the water-closet pans. "Of course, during intermission of water pressure, the flaws in the pipes represented by the 'leaks' would afford means for the entrance into the pipes of air from the soil, or from the neighbouring drains as the case might be, and doubtless of liquid also. I had myself opportunities of observing how considerable was the suction of air into the pipes at certain points after intermission of supply and on its renewal how much air coming with much noise and force had to be expelled. No special valves being provided for the purpose this air must have entered by accidental openings. At any time of intermission it is plain that the leaky water-pipes were at liberty to discharge their contents through any opening at a lower level and that they would convey not only such water as remained in them but those matters also which entered at the points of leakage. In short, the leaky pipes would act as so many means of draining the grou in which they were placed. Passing through or alongsid old rubble culverts they would take up foul air and liqu from these culverts and from the soil around and would deliver these matters at lower levels (if not during intermission, on the first renewal of supply) for consumption as 'drinking-water.' Intermission of water-current, however, is not by any means essential to the introduction of foreign matters into water-pipes. Under various physical conditions very powerful insuction of external matters into a full flowing water-pipe can take place. Some of these conditions were considered in a departmental report on Croydon in 1875. It results from the foregoing observations tha intermissions of the service large conta of the Oxford-street received but scanty notice in the text-books. Murchison had seen a few cases, Flint and Trousseau had not seen a case; Fagge, Reynolds, and Bartholow make no allusion to it; Welch[13] gives numerous references to the subject, but they are almost exclusively to continental and American observers.

Of the rarity of the complication there can be no doubt. Curschmann[14] in a large experience at the Leipsic clinic had seen (1898) two cases, occurring in the legs, both being unilateral, and he states that unilateral plugging is almost invariably the rule. Höltscher, quoted by Welch, does not report a single case in 2000 fatal cases of enteric fever at Munich, while Bettke in 1420 cases found only four, limited to the toes. A full discussion of the subject based on 1700 cases of enteric collected by Keen and Westcott of Philadelphia is to be found in a recent work by the former.[15] In 115 cases of typhoid gangrene which figure in this series 61 were of arterial, as distinct from venous, thrombosis, and of these 12 were bilateral, but not necessarily of the extremities. The legs, however, constitute the site of preference. Of 214 cases of gangrene of all varieties following typhus and typhoid fevers the lower extremities were affected in 126 cases. As regards time of occurrence the gangrene was found to occur most frequently during, or just after, the time of greatest cardiac weakness. Of 41 arterial cases 18 occurred in the second or third week. As regards etiology Keen is disposed to attribute the chief share to imperfect emptying of the cavities of the heart and to a sluggish circulation. In this connexion the case described above possesses interest as being closely illustrative of Dr. Keen's views.

It appears likely from the history of the case that a heart thrombus, probably lævo-ventricular, had formed during the period of observed cardiac asthenia and that by the exertion of raising the body the thrombus, or a portion of it, had been swept into the aorta. Impinging on the bifurcation of the aorta the clot was either broken into two portions of approximately equal size, one of which became impacted in each femoral about its middle third, or, being detained as a riding clot at the bifurcation, it became the nidus of a thrombosis which descended into the femorals and blocked them. To my mind the patency of the femorals at the groin for at least three days after the occurrence appears to favour the former supposition, but Dr. Michell Clarke is of opinion that the latter hypothesis is quite as likely to be the correct one. In a case recorded by Hayem, quoted by Keen, two days after observed alteration in the heart, symptoms of gangrene—viz., pain, with sensation of cold—commenced in the legs. Pulsation then ceased, first in the dorsales pedis, then in the popliteals, and finally in the femorals. Amputation subsequently showed, however, that though no pulsation could be detected the femoral was only partially blocked and a feeble circulation was proceeding. Here, then, even partial obstruction by an incomplete clot was accompanied by absence of pulsation at the groin.

If, finally, it be asked what light the femoral thrombosis throws on the question of diagnosis the answer must be—none.

Arterial thrombosis, according to Welch, though rare, is yet more common in influenza than in any other acute infection, and symmetrical gangrene following plugging has been frequently recorded. In discussing the etiology of these catastrophes Leichtenstern observes[16] that embolism as a cause of thrombosis must be taken into account in cases where aortic arterio-sclerosis or endocarditis is present in the course of influenza, but that even where no gross change can be detected clinically or anatomically the embolism may still occur by means of thrombi dislodged from the left side of the heart.

Devizes.

CHURCH SANITARY ASSOCIATION.—The Bishop of Stepney, speaking at a recent meeting of the National Health Society, said that the laws of health, no less than the principles of religion, represent the laws of God. The Church Sanitary Association has for 10 years been seeking to raise public opinion throughout the empire to this high level. Local honorary secretaries are wanted in all parts of the empire to help in the extension and deepening of the work of the association. Full information as to methods of working may be obtained at the London office, Church House, Westminster.

LARGE MALIGNANT GROWTH OF THE PYLORUS; POSTERIOR GASTRO-JEJUNOSTOMY; PATIENT IN PERFECT HEALTH 15 MONTHS AFTER OPERATION.

BY MAYO COLLIER, M.S. LOND., F.R.C.S. ENG.,
SENIOR SURGEON TO THE NORTH-WEST LONDON HOSPITAL, ETC.

A MAN, aged 43 years, was sent to me on March 7th, 1901, complaining of great emaciation, loss of strength, and inability to digest or retain anything but the smallest quantity of nourishment. His present illness dated back some two and a half years when he was troubled with vomiting after meals, flatulence, a heavy feeling in the stomach, and much distension. The bowels were always constipated. 18 months before he had been an in-patient at Guy's Hospital. There, he stated, he was dieted and treated with medicines and his stomach was washed out twice daily. Whilst there he improved but on leaving hospital the vomiting returned. At this time he was able to take more food and liquids but the vomiting and discomfort continued and he was palpably getting worse. He lost flesh rapidly, his usual weight being 11 stones 4 pounds. He was now only 8 stones 6 pounds. Whilst in Guy's Hospital he had learned to pass the stomach tube and wash out his own stomach. This he had done ever since three times a day as the only means of obtaining a small measure of comfort. His present condition was evidently one of extreme gravity and urgency. He was so weak that the exertion of walking from the cab to my consulting-room was followed by partial collapse. He was extremely emaciated and cadaverous in appearance and had evidently abandoned all hope of improvement or recovery. His family and personal history were unimportant except for the fact that he was said to have suffered five years before from peritonitis and inflammation of the bowels following what was described as a strain experienced during his arduous work as a blacksmith. Palpation and examination of the abdomen revealed a definite lump or hardness in the right epigastric and hypochondriac region of the size of a small fist. This apparently moved with the liver and was evidently a part of, and attached to, the pylorus. I was not satisfied that I could make out any definite enlargement of the stomach. A consultation was held with Dr. G. Herschell and my opinion was confirmed in every respect except that he was able to make out some considerable enlargement and proptosis of the stomach. We advised immediate operation as the only means of prolonging life.

The patient was admitted into the North-west London Hospital and there, with the aid of my colleague, Mr. J. Jackson Clarke, I performed the posterior gastro-duodenal, or, rather, gastro-jejunal, operation, thus short-circuiting the stomach. The growth was of considerable size, involving the pylorus and the adjacent part of the stomach to the extent of two or three inches. The pylorus with growth was firmly adherent to the liver and gall-bladder and the whole of the structures were matted together by old adhesions. The patient did excellently well and on April 27th he left the hospital much improved in weight, health, and appearance. Five months afterwards he was shown at a meeting of the Metropolitan Counties Branch of the British Medical Association held at the hospital. He weighed 12 stones, looked very fat and well, and expressed himself as quite fit, and said that he had returned to his work as a blacksmith. On May 29th, 1902, just 14 months after leaving the hospital, he reported himself as enjoying the best of health and strength and as quite well. He was doing a full day's work at the forge and was able to eat and to drink most kinds of simple food with ease and comfort. He looked the picture of health, though somewhat thinner than before. The growth could still be felt in the old position, not much, if anything, decreased, but there was no tenderness or pain.

The object of publishing this case is to accentuate the fact, well known to some hospital surgeons and physicians, that the course pursued by malignant growths in the abdominal cavity after operation differs essentially from what one expects to experience in other parts of the body. The malignant process appears to be arrested for a time. A stasis takes place in the activity of the growth. The barometer indicates a steady rise in the health, strength, weight, and activity of the patient. This patient could not have been in a worse possible condition short of death. His prognosis was apparently hopeless, yet 15 months after operation we find him enjoying the best of health, performing a full day's work of the most arduous character, and apparently as well as ever he was in his life. Operative interference in these cases does one of two things, both in themselves desirable—it shortens the misery by death or it prolongs the life by recovery.

Harley-street, W.

EOSINOPHILIA ASSOCIATED WITH HYDATID DISEASE.

BY C. G. SELIGMANN, M.B., M.R.C.P. LOND.,
SUPERINTENDENT OF THE CLINICAL LABORATORY, ST. THOMAS'S HOSPITAL;
AND
L. S. DUDGEON, M.R.C.P. LOND.,
ASSISTANT IN THE ELECTRICAL DEPARTMENT, ST. THOMAS'S HOSPITAL.

WE are indebted to Dr. Hector W. G. Mackenzie for permission to publish the following brief notes of a case under his care.

The patient, a well-nourished young woman from the east coast of England, aged 22 years, is one of a family of five children, all of whom, except herself, are stated to be healthy. There is a history of pulmonary tuberculosis on both sides of her family but she herself has always enjoyed good health until two years ago. Before that time she was in the habit of fondling a pet dog which constantly licked her hands. In December, 1900, and again in January, 1901, she suffered from attacks of pain in the right side which were considered to be due to pleurisy. Early in November, 1901, she suffered from abdominal pain which was not severe enough to prevent her following her usual occupation of nursery-maid. On Dec. 20th, 1901, she had malaise and pain in the region of the right shoulder which was so severe that she could not do her work.

On admission into St. Thomas's Hospital on Dec. 24th, 1901, her temperature was 101·2° F. By the evening of the 26th it had fallen to normal and remained so till Jan. 10th. There were enlargement of the right lobe of the liver and friction in the right axilla which suggested to Dr. Mackenzie the possible presence of hydatid disease. The patient's blood was examined on Dec. 27th at 11 A.M., about two hours after her last meal and gave the following results: Red cells, 6,290,625 per cubic millimetre; hæmoglobin, 70 per cent.; colour index, about 0·6; and white cells, 17,000 per cubic millimetre. A differential count of 500 white cells was as follows: polymorphonuclear neutrophiles, 22 per cent.; eosinophiles, 57 per cent.; lymphocytes, 20 per cent.; and basophiles, 1 per cent.

An operation was performed on Jan. 10th when 10 ounces of clear fluid, which contained hydatid booklets, were withdrawn from a cyst in the right lobe of the liver. The next day her temperature rose to 102 5° at midnight and continued to rise to this height nightly with morning remissions until the 18th. A second examination of the blood was made on the 13th. It showed 7000 leucocytes per cubic millimetre. A differential count showed: polymorphonuclear neutrophiles, 58 8 per cent.; eosinophiles, 12 per cent.; lymphocytes, 28 2 per cent.; and basophiles, 1 per cent. On the 16th it was noticed that the discharge from the cyst was copious and offensive and two days later it was purulent. At this time the temperature became normal for a couple of days; it then rose, and though fluctuating considerably for the next month, it was, on the whole, constantly high at night. Further hydatid cysts were evacuated through an incision in the right fifth intercostal space. A differential blood count was made on Feb. 20th, with the following results: polymorphonuclear neutrophiles, 60 per cent.; eosinophiles, 1 per cent.; lymphocytes, 29 4 per cent.; and basophiles, 0·6 per cent. At this time there was a considerable amount of purulent material draining from both wounds and a few collapsed cysts were also discharged. A blood count taken on March 13th, when the morning temperature was 102°, showed: red cells, 2,934,375, and white cells, 7600 per cubic millimetre. A differential count showed: polymorphonuclear neutrophiles, 73·2 per cent.; eosinophiles, 3·2 per cent.; lymphocytes, 22·2 per cent.; and basophiles, 1·4 per cent. On the 21st a further cyst was evacuated and a large quantity of clear fluid was withdrawn. On April 3rd the fifth examination of the blood was made when a differential count (200) gave: polymorphonuclear neutrophiles, 64·5 per cent.; eosinophiles, 1 per cent.; lymphocytes, 34·5 per cent.; and basophiles, *nil.* No urticarial rash was present at any stage of the patient's illness.

The chief interest of the case centres in the high percentage of eosinophiles present. The number found in the first count is in excess of any records which we have been able to find, with the exception of a case of trichinosis under the care of W. Osler,[1] in which the blood was examined by T. R. Brown and the eosinophiles were found to number 68 per cent. in a total leucocytosis of 1700, and a case of ankylostomiasis examined by Bücklers,[2] in which the eosinophiles numbered 72 per cent. It is most nearly approached by certain other cases of trichinosis and in bronchial asthma at the time of the paroxysms. In the latter complaint Billings[3] reports counts of 53 6 per cent., 38·2 per cent., and 33·9 per cent. eosinophiles in three cases in which the total leucocyte count was not increased. As is well known eosinophilia—for the most part of slight degree—occurs in a number of diseases, especially, according to Neusser, in pemphigus, in most non-malignant diseases of the liver, and "in trouble involving the female genitals, especially the ovaries."[4] Further, Neusser considers "that the increase of eosinophiles which he finds in hydatids serves to distinguish them from hydronephrosis, dilated gall-bladder, &c."[5] Recently Lovell Gulland[6] has shown that marked eosinophilia occurs in filariasis and his results have been confirmed by Coles[7] who, further, in a case of bilharzia disease occurring in an otherwise healthy and athletic Englishman, found that 20 per cent. of the leucocytes present were eosinophiles. None of the causes enumerated above were present in the case which we describe, with the possible exception of ovarian trouble, which might perhaps be considered to have been present since the patient had not menstruated for a few months preceding admission to St. Thomas's Hospital. We do not, however, think that this last-mentioned factor, even considering it to have existed, could have caused the enormous increase of eosinophiles found, and it seems alike simpler and more rational to regard hydatid disease as the cause of the blood change, more especially as the number of eosinophiles present gradually dropped to normal after operation. Again, it is interesting to note that, according to Bückler, "all kinds of helminthides, from the harmless oxyuris to the pernicious ankylostoma, may bring about an increase of the eosinophile cells in the blood, often to an enormous extent." The author makes no mention of hydatid disease.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF RABIES LATENT FOR 20 MONTHS.

BY HOWELL REES, L.R.C.P. LOND., M.R.C.S. ENG.,
AND
D. O. ROWLANDS, L.R.C.P., L.R.C.S. EDIN.

ON August 9th, 1900, a powerful, mountain-bred man, 63 years of age, was bitten on the metacarpo-phalangeal joints of the thumb and forefinger of the left hand by a fox terrier which hung on to his hand. In his attempts to free himself the wounds were considerably lacerated and were cauterised with nitrate of silver by one of us on the patient's arrival at the surgery. A little boy was also bitten on the leg by the same dog on the same day. The dog was shot and buried the same evening. An attempt was made to get the Board of Agriculture to exhume the carcass and to examine the head, and after a great deal of circumlocution and in reply to an urgent request to relieve the suspense of those bitten, the secretary wrote that decomposition would be now too advanced to allow of inoculation experiments being of any value. It was then determined to give the patients the benefit of the doubt as to whether the dog was suffering from rabies or not and to send them to Paris for treatment at the Pasteur Institute. But further delay was caused by the necessity of collecting subscriptions to defray the expenses and of writing to Paris to arrange for accommodation for the patients at a hotel, so that it was August 29th when they started on the journey. The man was under treatment at the institute for 19 days, and he returned home feeling as well as ever, and remained so until May 26th, 1902, when he complained to some of his friends of pain in his left arm, and on the morning of the 27th he visited one of us at his surgery complaining of pain in the left arm and in the stomach and of sickness. On trying to swallow the medicine given to him he found that he could not do so owing to the painful spasms caused by the attempt. On the evening of the same day he walked one and a quarter miles with a friend and a brother to see one of us, and he was then (6 P.M.) in a state of semi-collapse, with a cold clammy skin, a small rapid pulse of over 120, an expression of terror on his face, and frequent spasms of the muscles of deglutition and respiration, accompanied by deep sighs and groans and startings to his feet and gasping for breath, with the shoulders raised and the chest expanded. He was ordered to return home and to go to bed immediately, the brother being privately informed that he was suffering from rabies. We attended him and gave him a hypodermic injection of a quarter of a grain of morphine and atropine which was repeated twice up to 3 A.M. the following morning (the 28th), when the patient was raving mad, requiring five men to hold him down, and we suggested that chloroform might be administered. On returning with some chloroform we found that he was now under the influence of the narcotic and in a state of semi-consciousness; he recognised us with a faint smile but immediately relapsed into the terrorised expression of face, with the spasms still continuing though with lessened severity. An enema of gruel and one drachm of chloral hydrate were now given and later, as the spasms and restlessness continued, a hypodermic injection of hyoscine was given, but in the course of two hours or so another quarter of a grain of morphine had to be given. His temperature at 4 A.M. was 102° F. and his pulse-rate was 132. There were intense thirst and total inability to swallow anything to quench it, the sight of any fluid causing spasms; there were also great intolerance of light (photophobia) and hyperæsthesia. There was a wild expression of the eyes with protrusion of the eyeballs which were very bloodshot. While lying in bed he would suddenly spring up on his feet and then lie down again, wrapping the bedclothes around him. The saliva was not swallowed, as it ran out at the corners of his mouth. The slightest draught of air also disturbed him. His daughter-in-law attempted to wash his feet but as soon as the water touched him he started violently and she had to desist. He continued in very much the same condition throughout the day and and was seen to be getting weaker every hour, but he never lost complete consciousness and died without any convulsions at 8.30 P.M. No post-mortem examination was made.

Notwithstanding the blundering policy of the Board of Agriculture in delaying the examination of the carcass of the dog until too late, there could be no reasonable doubt that the dog was rabid. It was ascertained that it had bitten several people near its home, and a cow also bitten by it had died and also, it is said, several cats in the establishment of its owner had also died after being bitten. Whether the result would have been different if the man could have been sent to Paris immediately after being bitten it is impossible to say.

It has been to us a cause of wonder for some time why an institute similar to the Pasteur Institute in Paris should not have been established in London long ago. It was no light matter for these poor people from the Amman Valley, Carmarthenshire, knowing no language but their native Welsh and never having been outside their own country before, to undergo the long and tedious journey to Paris and back. Had there been a Pasteur institute in London patients from any part of the British Isles could be under treatment within 24 hours, at a trifling expense, and be independent of the red-tapeism of the Board of Agriculture. New York, St. Louis, and Kasauli, India, have their Pasteur institutes, and why not the greatest city of them all—London!

Glan-Garnant, South Wales.

CASES OF MULTIPLE EXOSTOSES.

BY A. E. FRANCIS, M.R.C.S. ENG., L.R.C.P. LOND.,
HOUSE SURGEON, ROYAL PORTSMOUTH HOSPITAL.

A BOY, aged six years, suffering from a sprained wrist, was brought by his father to the casualty department of the Royal Portsmouth Hospital. Upon examination a tumour was detected at the lower end of the right radius, near the junction of the epiphysis with the diaphysis. This was found upon manipulation to be a hard and painless pedunculated growth apparently springing directly from the bone. At the inner side of the upper end of the right humerus there was another tumour projecting visibly beneath the skin. It was about one and a half inches in length, smooth and slender, but expanded and tuberculated at its extremity. A still further examination of the child revealed similar outgrowths in the following situations: the acromial end of the right clavicle, the sternal end of the sixth rib on the right side, the lower ends of the right and left femora, and the upper ends of the right and left tibiæ. That on the rib was flattish and more sessile but the others were distinctly pedunculated. Those upon the femora took origin just above the internal condyle and projected upwards, whilst those upon the tibiæ arose from the internal tuberosity and projected downwards. The child was healthy and well nourished and showed no signs of rickets. The father was similarly affected and tumours were found at the upper end of the right humerus, the sternal end of the eighth rib on the right side, the lower ends of the right and left femora, the upper ends of the right and left tibiæ, and the lower end of the right tibia. He volunteered the information that the "lumps" had increased in size when he was a child but that when he became a man they had ceased to grow. They never caused him any inconvenience. He also said that his father had them too. His wife was quite healthy. They had no other child.

There is no doubt that these tumours were exostoses of the cancellous or spongy type. I think that the cases are of interest from the very well-marked hereditary history, the multiplicity of the tumours, and the degree of symmetry that existed between the outgrowths of opposite sides.

Portsmouth.

A RAPID AND SIMPLE METHOD OF LOCALISING FOREIGN BODIES BY THE X RAYS.

BY J. WISHART LITTLE, M.B., L.R.C.P. LOND.,
M.R.C.S. ENG.,
LIEUTENANT, INDIAN MEDICAL SERVICE.

THE method of localising foreign bodies described by Mr. W. R. Fox in THE LANCET of Sept. 21st, 1901, p. 784, is doubtlessly mathematically correct, but it is too tedious and complicated to be of great practical use when expediency is an important factor. The following may be worthy of note to those interested in x-ray work, but it is certainly of importance in military surgery, especially in active service, where time and means of transport are both limited.

The patient is placed on a couch or a table fitted with the usual drum and cross-wires in such a position as to allow the foreign body, the presence of which has previously been determined by means of the screen, to be as nearly as possible over the meeting point of the wires. The vacuum-tube is fixed at a height of 15 or 20 inches, according to the thickness of the part to be radiographed, measuring from the plate to the anode and as nearly as possible vertically over the crossing point of the wires. This position of the tube is known as the zero point. Two photographs are now taken on one negative, the first exposure being given from a point two inches to one side of the zero. The tube is then moved through a distance of four inches to a point two inches on the other side of the zero, in a horizontal direction, from which the second exposure is given. On developing the plate the cross wires and two shadows of the foreign body are seen. By means of a sliding caliper scale, which I have had specially engraved for the heights of 15 and 20 inches, the actual depth of the foreign body from the plate may immediately be read off from the instrument, after placing the fixed jaw of the scale on one part of the first shadow and sliding the moveable jaw along till it points to the corresponding part of the second shadow.[1] It is often, however, found advisable in cases where the foreign body is less than one inch from the surface to increase the distance through which the x-ray tube is moved to eight inches instead of four inches (i.e., four inches on each side of the zero), By this means the distance between the shadows is increased and consequently a more accurate result obtained but with some distortion of the images. Of course, it must be remembered that by doubling the distance through which the tube is moved the reading on the scale must be halved to give the true depth of the foreign body from the plate.

In rapid work, when great accuracy is not required or when photographic plates cannot be obtained, the screen, fitted with cross wires and a thin sheet of transparent celluloid on which the shadows may be marked, is employed in exactly a similar manner. In using the screen, however, it is advisable to work with a distance of only 10 inches (measuring from screen to anode) instead of 20 inches. The reading on the 20-inch scale must necessarily be halved to obtain the true depth of the foreign body from the screen. It must, nevertheless, be admitted that localisation by this means is not as satisfactory as when negatives are employed since the shadows are generally lacking in definition. It is obvious that this direct-reading localising scale, which only measures eight inches in length, has a great advantage over the other and more cumbersome localisers in use.

The above method is founded on the principle described by Mr. J. Mackenzie Davidson but it is more compact and simple.

ST. GEORGE'S HOSPITAL.

AN UNUSUAL CASE OF INTUSSUSCEPTION; OPERATION; RECOVERY.

(Under the care of Mr. H. S. PENDLEBURY.)

WE have published in the "Mirror of Hospital Practice" numerous cases of intussusception in which early operation was successful in saving life. The following case is a valuable addition to the series, for it demonstrates clearly the utter unlikelihood of a reduction of the invagination by any method of injection or inflation. The indurated iliac intussusception which was last reduced could be amenable only to direct surgical treatment. The practice of employing inflation or injection for the reduction of an intussusception is yearly less frequently seen and the value of an early laparotomy is more and more recognised. The best results will be obtained when the public have learnt the importance of the early symptoms of the disease and the danger of purgatives. For the notes of the case we are indebted to Mr. Adrian Caddy, house surgeon.

A boy, aged two years, was admitted into St. George's Hospital on Dec. 29th, 1901. The child had had a large meal of nuts on the 26th; in the afternoon of the 28th he was seized with sudden acute abdominal pain, followed by vomiting, and in a few hours' time by the discharge of much mucus and some blood from the rectum. The vomiting and rectal discharge continued and Dr. G. E. Hale was called in. He diagnosed intussusception and advised immediate removal of the child to St. George's Hospital.

On admission the patient was a bright, healthy-looking child who sat up in bed and did not seem to be much distressed. His pulse was 144 and his temperature was 99 6° F. On examination of the abdomen, movement of the parietes was free; there was little distension and on palpation no rigidity of the abdominal muscles or marked tenderness was noted, but a rounded, sausage-shaped tumour, dull on percussion, was detected extending from the right iliac fossa to the region of the umbilicus and freely moveable. Rectal examination elicited nothing except some mucous discharge. The child vomited some brownish-coloured fluid on two occasions after admission. Mr. Pendlebury was sent for and he decided on immediate operation 26 hours after the onset of acute symptoms. Ether on a cone was the anæsthetic chosen, and the abdomen was opened through a two-inch incision below the umbilicus in the right rectus muscle. The tumour was at once seen and was lifted out of the abdomen; it was about six inches in length. It showed only a slight degree of congestion and was reduced with little difficulty. After reducing the intussusception which was of the commoner ileo cæcal variety, there was exhibited about two inches from the cæcum a second intussusception of the ileum from one to two inches long; this also was easily reduced. At this spot the infiltration and thickening of the intestinal wall were greatest. The abdomen was closed with fish-gut sutures which were removed 10 days later when the wound was quite healed. The operation lasted 20 minutes The bowels acted naturally on the third day and abdominally nothing abnormal afterwards occurred.

The patient had been suffering from a slight cough for a few days before admission and, possibly as a result of the ether anæsthesia, he developed a severe attack of bronchitis with a troublesome cough which did not subside for 10 days. The temperature during this time fell gradually from 102° to normal and thus for some while his condition occasioned considerable anxiety. He was discharged 24 days after the operation and was seen again on Feb. 20th, when the scar seemed to be quite firm.

Remarks by Mr. CADDY.—The case is interesting on account of the very unusual type of intussusception and the slight injury which the peritoneum had received, and the length of time which had elapsed between the onset of symptoms and the operation (26 hours). The absence of collapse or of abdominal pain was marked and one would expect in an intussusception of this nature more acute symptoms.

Remarks by Mr. PENDLEBURY.—The chief point of interest in this case lies really in the actual anatomy of the intussusception. Clinically it might be described as a "typical case," for it presented all the usual phenomena expected in acute intussusception, from the history of the previous indigestible meal of nuts to the existence of a definite tumour. Perhaps, however, one might mention that the child looked remarkably fit and well considering his condition. This case, I think, comes under the variety denominated iliaco-ileo-colica by Leichtenstern.[1] I should say that the small intussusception of the ileum occurred first and acting possibly as an irritant tumour caused the further and far more usual ileo-cæcal form. Certainly, after reduction, which was easily accomplished, the stiffest and most infiltrated and inflamed part of the gut was the few inches occupied by the enteric intussusception. The case admirably illustrates the advantages of early diagnosis and immediate surgical treatment.

MONKWEARMOUTH AND SOUTHWICK HOSPITAL.

A CASE OF AMPUTATION OF THE RIGHT SHOULDER AND THE RIGHT HIP.

(Under the care of Dr. P. A. PEARCEY.)

SIMULTANEOUS or rapidly consecutive amputations of two limbs are always noteworthy when the limbs are removed at a high level. Most commonly the lower limbs are the seat of double amputation, for it is more likely that both legs will be irreparably damaged than that both arms or one leg and one arm will be thus affected. In the following case the arm was amputated at the shoulder-joint and the thigh at the hip-joint, and it is probable that in this respect the case is without parallel. Several cases are on record where portions of three limbs have been amputated[1] but much less of each limb was removed than in the case recorded below. For gangrene portions of all four limbs have been amputated.[2] For the notes of the case we are indebted to Mr. Allan Walker, late house surgeon.

---

[1] Treves. Intestinal Obstruction, p. 145.

A girl, aged 17 years, was admitted to the Monkwearmouth and Southwick Hospital on Nov. 18th, 1901, suffering from the result of an accident caused by her dress having become caught in between two small cog-wheels whilst she was oiling some machinery. On admission she was suffering from great shock but was conscious. Her right arm and right thigh were severely smashed and mutilated and though both brachial and femoral arteries were torn no tourniquet had been applied and there was little or no hæmorrhage—in fact, the limbs were merely hanging by small skin attachments. On seeing the patient, an hour after the accident, as she had been brought over two miles in a cart to the hospital, Dr. Pearcey at once decided to amputate both limbs. Amputation at the shoulder-joint was first performed. Owing to the mutilation some difficulty was experienced in obtaining flaps but a little manipulation overcame this. This having been accomplished Dr. Pearcey proceeded to amputate the right leg at the hip-joint, when the same difficulty of obtaining adequate flaps was present. Before commencing each amputation Dr. Pearcey ligatured the axillary and femoral arteries respectively. Chloroform was at first administered as an anæsthetic but this was soon changed to ether, only sufficient being given to keep the patient unconscious. Immediately on admission she was given one-thirtieth of a grain of strychnine and half a drachm of ether hypodermically. During the operation signs of heart failure commenced and a further hypodermic injection of one-tenth of a grain of strychnine was given. After the amputation at the shoulder was completed these symptoms reappeared and she was infused with three pints of saline solution, one drachm to the pint, at a temperature of 100°F. This was done whilst the amputation at the hip-joint was proceeding The operation lasted one and a half hours. The accident had occurred at brickworks and the parts required extensive cleansing. The girl had been swung round and round with the wheel and each time the limbs came in contact with the ground the tissues became embedded with clay and earth, so that it was impossible to obtain clean flaps free from earthy matter. Primary union was consequently not expected; in fact, the girl's condition appeared perfectly hopeless. Despite this the shoulder did practically heal by first intention. The hip gave more trouble; it suppurated but slowly healed. The after-treatment was simply that required by such a case—free drainage, stimulants, and generous diet.

Remarks by Dr. Pearcey.—The main points of interest in this case are the following: (1) that the girl escaped hæmorrhage; (2) that she survived the operation; and (3) the unique nature of the condition, both arm and leg being amputated at the shoulder- and hip-joints respectively on the same side of the body. I should be glad to know how many similar cases have been recorded with the same happy result.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Changes in the Bone Marrow associated with Suppuration within the Knee-joint.—Neuro-lipomata of the Median Nerve.—"Chyle" Cyst of the Mesentery.—Dermoid Cyst of the Inguinal Canal.—Meningococcus in a Case of Cerebral Tumour.—Tuberculosis in a Python.—Exhibition of Specimens.

A meeting of this society was held on June 17th, Mr W. Watson Cheyne, C.B., the President, being in the chair.

Dr. A. G. Phear read a paper on the State of the Bone Marrow of the Femur in a case of Suppuration of the Knee-joint, followed by Profuse Secondary Hæmorrhage. The changes in the medullary tissue were of a double order; there was (1) proliferation of myelocytes and allied cells similar to that which had been recorded in other cases of infective processes and constituting the so-called "myelocytic reaction" to infection; and (2) proliferation of cells of the erythroblastic type, of special interest when viewed in connexion with the severe hæmorrhage that took place some days before death; the characters of the erythroblasts were such as to denote an early stage in their growth. Giant cells were present in considerable number. The proliferation of the cellular constituents of the marrow had advanced to such a degree as to transform its general character; in the place of a tissue consisting almost wholly of fat there was found an opaque, firm, reddish tissue containing an insignificant amount of fat and composed chiefly of the various cells described. Reference was made to recent investigations into the marrow changes attendant on experimentally induced infection with pyogenic organisms and stress was laid on the close similarity between the results of experiment and the marrow lesions which in the present case were found to be clinically associated with suppuration. The importance of such observations, both clinical and experimental, lay in their bearing on the view that the bone-marrow was the source of the polymorphonuclear blood corpuscles, and therefore the chief tissue concerned in the leucocytosis that accompanied infective diseases.—Dr. H. Batty Shaw remarked on the absence of karyokinesis in the cells of bone marrow as observed by Dr. Phear. How was this to be brought into line with the view that bone marrow was the place of origin of the leucocytes?—Dr. Phear, in reply, said that no blood examination was made because the case did not come under his notice until after death. In regard to the absence of nuclear changes in the cells other observers had found karyokinetic figures and their absence in this case did not negative the origin of leucocytes from bone marrow.

Mr. H. J. Waring narrated a case of Neuro-lipomata of the Median Nerve occurring in a man aged 38 years. The patient had been quite well until June, 1895, when the right hand and forearm had been crushed by a heavy bar of wood. One year later he suffered pain in the hand and arm which continued until October, 1900, when he was first seen, and resulted in a considerable enlargement of the thumb and forefinger. Amputation was performed in April, 1901, and a diffuse lipomatous growth was found to have formed along the peripheral branches of the median nerve which was also found to be thickened in the forearm. The amputated hand and a skiagram of it were exhibited.—Dr. H. Morley Fletcher suggested the possibility of the case having some relation to von Recklinghausen's disease and asked if there were any tumours along the nerves or pigmentation of the skin in other parts of the body. Was it not a fact that the lipomatous growth had recurred in the limb since the amputation?—Mr Waring, in reply, said that there were no tumours in any other part of the body.

Dr. John Fawcett exhibited a "Chyle" Cyst of the Mesentery, which had produced intestinal obstruction in a child, aged three months, who was admitted into Guy's Hospital on Dec. 13th, 1902, and died the next day. He had been well till Dec. 11th, when diarrhœa and vomiting commenced and continued. At the necropsy an acute intestinal obstruction was found, due to a cyst which had caused a kinking of the small intestine. The cyst was a unilocular one, of the shape of a pear, and it was distended with a milky fluid. The glands in the mesentery were enlarged. The analysis of the fluid by Mr. J. H. Riffel showed it to be chyle. It contained coagulable proteids and 7 7 grammes per 100 cubic centimetres of fat. The reaction was alkaline. Sections made from two pieces of the cyst wall showed it to be composed of fibrous and muscular tissue. The characters of this cyst, both as regard its position, contents, and structure, were similar in many ways to those described by Eve,[1] Moynihan,[2] and others. The classification previously adopted, based largely upon the contents of these cysts, was not thought satisfactory The nature of the contents was more or less a matter of chance. The most satisfactory plan would be to classify them all as of embryonic origin (as suggested by C. Dowd in the Annals of Surgery, vol. xxxii., 1900), arising by sequestration from the intestine or its neighbourhood, some from mesoblastic tissue having fibrous or muscular walls or both, others from hypoblast tissue as well, and therefore showing epithelial structures.

Mr Herbert Paterson showed a Cyst removed from the

[2] Annals of Surgery, vol. xxvi., p. 1.

Inguinal Canal of a man, aged 35 years. A swelling thought to be hernial had been noticed for five years. Shortly before its removal the swelling had suddenly become painful and an attempt had been made under an anæsthetic to reduce it. On opening what was thought to be a hernial sac thick pultaceous material escaped. Further examination showed the swelling to be a closed sac, not communicating with the abdominal cavity. On dissecting it out it was found very adherent to the surrounding structures. At its inner part it was attached to the front of the symphysis pubis by a fibrous band. One hair was detected growing on the wall of the cyst. Microscopical examination showed the cyst to be lined with skin. Mr. Paterson commented on the rarity of dermoids in this region and referred to a similar case recorded by Mr. A. Pearce Gould in THE LANCET of Nov. 4th, 1893, p. 1126. He had been unable, however, to find any case in which the supposed nature of the cyst had been verified by microscopical examination.

Dr. CLIVE RIVIERE read a paper on the Meningococcus in a case of Cerebral Tumour Simulating Posterior Basic Meningitis. The case occurred at the Shadwell Children's Hospital. A male child, aged nine months, suffered with head retraction and progressive hydrocephalus with a spastic condition of the limbs and died after an illness of four and a half months. A diagnosis of posterior basic meningitis had been made, but at the post-mortem examination no meningitis was found, only a large caseous tumour in each corpus striatum, that in the left being the larger and extending back into the pons, obstructing the Sylvian aqueduct and giving rise to extreme hydrocephalus. In this pent-up fluid was found a diplococcus (isolated on three occasions; twice from fluid obtained during life and again at the post-mortem examination), the morphological and cultural characteristics of which pointed to its being a variety of the meningococcus. The discovery of this organism during life had seemed to confirm the diagnosis of posterior basic meningitis. Dr. Riviere pointed out that though the meningococcus had been isolated from cases of tuberculous meningitis he had not been able to find a case in which it had been found under the conditions described above.

Mr. S. G. SHATTOCK recorded an instance of Tuberculosis in a Python, and a portion of the creature's gullet was exhibited. The lesions of unusual character were those of the œsophagus, in the mucosa of which there were a series of oval swellings, each consisting of a compact aggregate of small spherical tubercles. No such lesion was met with in the human subject, in whom tuberculous disease of the œsophagus was known only as a result of direct extension from neighbouring structures. The peculiar lesions in question were explained by the fact that in ophidia there occurred normally in the mucosa of the œsophagus oval lymphatic nodules or "glands" like those of the intestine; they lay immediately beneath the epithelium which was of the columnar-celled variety. Mr. Shattock viewed the infection as direct and due to the consumption of tuberculous food, the main lesion being in the stomach. The food consisted of ducks and the bacillus was probably avian in source. Acid-fast bacilli were demonstrable in the œsophageal lesions. Mr. Shattock observed that there was no trace of ulceration over these lesions, the infection having occurred between the cells of an intact epithelium. It was not so much that the bacillus had selected the site as that the sites had selected the bacillus. The process was a transport of bacilli by wandering cells like that of inhaled inorganic particles to the bronchial glands. As regarded the temperature it had long been known that the tubercle bacillus would grow at comparatively low temperatures, and as the python in question had lived in an atmosphere of 70° F., the temperature of the water in its tank being as high even as 80° F., the growth of the bacilli offered no difficulty though occurring in a "cold-blooded" creature.

Mr. WARING exhibited: (1) A Congenital Lipoma of the Face and (2) a Congenital Tumour of the Superior Maxilla.

OBSTETRICAL SOCIETY OF LONDON.

Pregnancy after Removal of Both Ovaries for Cystic Tumours—Primary Ovarian Gestation.—Exhibition of Specimens.

A MEETING of this society was held on June 4th, Dr. PETER HORROCKS, the President, being in the chair.

Mr. ALBAN H. G. DORAN read a paper on Pregnancy after Removal of both Ovaries for Cystic Tumour. A woman, aged 25 years, after bearing one child, underwent ovariotomy for a multilocular adenomatous cystic tumour of the left ovary. She then bore four more children and afterwards, when 39 years of age, came under Mr. Doran's care and he removed a similar tumour of the right ovary. The base required enucleation, part of the capsule was ligatured like a pedicle with silk, and the greater portion was cut away, but in that part no trace of the Fallopian tube could be detected. A small tubercle on the left of the uterus was the sole remnant of the left appendages. After convalescence the period recurred and continued till the patient became pregnant and bore a child at term two years after the operation. The period then returned and ceased abruptly when the patient was 45 years of age. The consequent menopause symptoms were distinct though mild. Mr. Doran briefly reviewed a few cases, already reported, where pregnancy ensued after the removal of both ovaries for tumour or chronic inflammatory disease. In a case recorded by Schatz, in which both ovaries were removed for cystic tumour, one tube and a piece of ovarian tissue were purposely left behind. Five years later the patient gave birth to a child at term. Stansbury Sutton of Pittsburgh reported a case in which both ovaries were removed for cystic disease; the right pedicle was severed by cautery, the left by scissors. The patient was twice pregnant afterwards. Dr. Gordon of Portland, Maine, U.S., removed both tubes and ovaries for inflammatory disease and the patient was delivered of a child two years later. Other reported cases were doubtful. The presence of ovarian tissue was essential in these cases. In Mr. Doran's case it was probably a detached area lying in the right ovarian ligament; the cyst itself was certainly enucleated entire. Mr. Doran suspected that the Fallopian tube escaped ligature and removal altogether, the base of the tumour being enucleated from the posterior layer of the broad ligament. The condition after operation would then be as in Schatz's case, the tube remaining entire. It was not absolutely certain, however, that the tube was not included in the ligature and in the part removed. This occurred in the cases of Stansbury Sutton and Gordon and reference was made to a case where pregnancy occurred after Cæsarean section and ligature of both tubes with silkworm gut for "sterilisation" (Galabin-Horrocks). The ligature might either loosen or perhaps ulcerate through the tube, which managed to heal behind it without stricture of its canal. The tube might then resume its functions, even if reduced to a stump.—Mr. J. BLAND-SUTTON observed that Mr. Doran's interesting communication really raised two important questions for consideration—namely, the occurrence of pregnancy after double ovariotomy and the effect of a ligature on the continuity of the lumen of a Fallopian tube. Probably no one in England had studied so closely the "fate of the ligature" after successful ovariotomy as had Mr. Doran, and he certainly was the first to study the changes which took place in the stump of the pedicle after intra-peritoneal ligature. It was now quite certain that when a Fallopian tube was ligatured in continuity it did not necessarily permanently obliterate the tubal lumen. In his Cæsarean section for pelvic contraction Mr Bland-Sutton in 1891 tied the Fallopian tubes with thin silk within an inch of the uterus; this patient had remained sterile. On a subsequent occasion, where it was deemed prudent to induce labour for uncontrollable vomiting and epileptic seizures, an attempt was made to sterilise the patient by drawing out each tube and transfixing the mesosalpinx with a needle armed with thin silk and then tightly tying the tube near its middle. This failed, for the patient quickly conceived again and had reconceived many times, though her constitutional condition had never allowed a pregnancy to go to term. Since this experience Mr. Bland-Sutton had always tied the tubes in two places and exsected a piece of the tube when it was desirable to sterilise a patient. Mr. Doran's suggestion that "the ligature might perhaps ulcerate through the tube which then healed behind it without stricture of its canal" was probably true, and the following case in a measure supported it. In 1898 Mr. Bland-Sutton removed an ovarian cyst; its very slender pedicle was tied with thin silk. Although recovery was uneventful the patient complained during many weeks of cramp-like pain on the side from which the cyst had been removed. The pains gradually passed away and 10 months later during menstruation the patient accidentally noticed on her napkin a tiny loop of silk which she saved. This was the loop of silk used to secure the Fallopian tube; it had ulcerated into the tube and had been very slowly conducted into the uterus and so had escaped. A silk ligature applied to the cut end of a ureter in the course of a nephrectomy was sometimes conveyed to the bladder in the same manner. Mr. Bland-Sutton was glad to have the opportunity of stating that the opinion which he expressed to the society in 1892 had not been borne out by subsequent experience, and it was now abundantly clear to all that the mere application of a silk ligature to the Fallopian tubes could not be depended upon to obliterate permanently their lumina and thus prove an obstacle to pregnancy.—Dr. A. L. GALABIN said that he had met with two cases in which the attempt to sterilise by tying the Fallopian tubes had failed and which were those referred to by Mr. Doran. In that in which Dr. John Shaw had tied the Fallopian tubes with silkworm gut in performing Cæsarean section it was certain that the ovum had passed by the tube on which the ligature appeared to remain *in situ*, for on the side on which the ligature had cut through and the tube was divided the divided ends were absolutely closed. In the second case he had himself in performing Cæsarean section tied the tubes with kangaroo tendon and the patient became pregnant again within a year or so. Taught by the experience of these cases he had since then adopted the plan of cutting a piece out of the tubes between two ligatures, then pulling out the stump on each side as far as possible and cutting it off so that the open lumen was left at the bottom of an inverted cone of cellular tissue. None of the patients so treated had become pregnant again and he was inclined so far to regard this as a trustworthy method.—Mr. A. O. BUTLER-SMYTHE asked Dr. Herbert R. Spencer if he could give any information relative to the pregnancies of Mr. Bland-Sutton's patient. She had attended the Samaritan Hospital and had stated that subsequent to the operation she had twice miscarried with twins, which rather surprised her inasmuch as all her previous pregnancies had been single. He also wished to know if the fits had been benefited by the operation.—The PRESIDENT had expected to hear a hot discussion on how pregnancy could have taken place when both ovaries had been removed; but Mr. Doran had frankly admitted that a piece of ovarian tissue had been left behind at the second operation, so that there was nothing strange about the case. He was surprised to hear Mr. Doran advocate the removal of both ovaries entire when it was possible to leave a healthy piece. He thought it better to leave some ovary whenever possible.—Dr. AMAND J. M. ROUTH thought that sufficient cases could now be collected to explain the occasional occurrence of menstruation and ovulation after double ovariotomy, and he observed that in most of the reported cases a latent period of a few months or even years elapsed before menstruation again appeared. He thought it likely that a small piece of the hilum of one ovary might be left containing no Graafian follicles sufficiently developed to come immediately to maturity. He believed that such a piece of ovarian stroma, together with the follicles, became in a few months further developed, and ovulation and menstruation then recurred.—Dr. R. BOXALL remarked on the impossibility of making absolutely sure that sterility would necessarily result from ligature of the Fallopian tubes. The importance of the question often arose when operation was undertaken and the tubes were at the same time ligatured with the object of rendering the woman sterile; but it might also arise when from disease of the appendages operation was indicated. For instance, he had recently met with a case in which, owing to long-continued and recurrent attacks of inflammation, it became necessary to urge surgical interference with the appendages. To this procedure objection was raised both by the patient and by her husband solely on the ground that complete removal of the appendages would entail sterility. In that event cohabitation would be forbidden by their church. Eventually the symptoms became so urgent that operation was rendered imperative. Fortunately, it was found possible to retain a healthy part of one ovary, in consequence of which the menses had not been discontinued. Notwithstanding that the greater part of both tubes as well as one ovary and part of the other were of necessity removed no occasion arose for the separation, which they both so much dreaded, for it was possible to assure them that impregnation was not, by the operation at any rate, put beyond the bounds of possibility.—The paper was also discussed by Dr. HERBERT SPENCER and by Dr. W. JAPP SINCLAIR.—Mr. ALBAN DORAN, in replying, said that he was much interested in the discussion on attempts to sterilise a patient by tying or cutting the Fallopian tubes. He believed that in his own case a trace of healthy (not cystic) ovarian tissue was left in the right ovarian ligament. It was easy to extirpate all ovarian tissue when the ovaries were taken away with the uterus and not difficult when a pedunculated ovarian cyst was removed, as the ovarian ligament was elongated and very prominent. But when the base of the cyst burrowed and lay close against the uterus the ovarian ligament could rarely be distinguished. In one case where Mr. Doran was obliged to remove the uterus with the burrowing adherent tumour he found on examining the specimen that it would have been practically impossible to leave the round ligament or part of a pedicle without leaving also ovarian tissue, morbid or healthy. As it was with a cystic tumour, so it was with inflamed adherent appendages, and so it very often was with an ovary removed to check the growth of a uterine fibroid. In all these cases the operator dared not cut the pedicle sufficiently short to remove all ovarian tissue, for he knew that if he did so the ligature would probably slip. Hence it was not very hard to understand that in some cases menstruation or even pregnancy occurred after removal of both ovaries. In his own case the ovarian ligament with some healthy tissue had probably been flattened against the uterus and had thus escaped the ligature. After-histories of all abdominal operations were valuable, especially as to the fate of ligatures which were shed sometimes eight or 10 years after they had been applied.

Mr. A. W. MAYO ROBSON contributed a short communication on a case of Primary Ovarian Gestation. He pointed out that though he had operated on about 50 cases of extra-uterine gestation the present specimen was the only one of the series in which he had been able to prove ovarian gestation. Doubtless many of the cases described previously as ovarian pregnancy had been of that nature, but this was apparently only the fourth case in which absolute proof had been furnished by showing an early embryo in its membranes and contained in a sac in the ovary. The patient, who was 24 years of age, was admitted to the Leeds General Infirmary on April 11th, 1902, in a state of profound collapse. She stated that on the previous night, six weeks after her last menstrual period and a fortnight after missing her menses, she was seized with a sudden pain in the right side while engaged in blackleading a grate. She became very faint and pallid and soon she vomited. She was put to bed but the pain continued during the night and was much worse next morning. The pallor also increased. She was seen by her medical attendant (Mr. H. Towers) who diagnosed extra-uterine gestation and advised her removal to the infirmary. She said that she was a married woman but had never had any children. On admission the patient was very pale indeed. Her temperature was 98° F., the pulse was 130, and the respirations were 48. She complained of pain on the right of the abdomen, which was distended and did not move on respiration. It was very tense and tender, rendering palpation difficult, but a fluid thrill could be obtained on flicking with the finger. No tumour could be felt. Examined per vaginam the uterus was found to be fixed and Douglas's pouch was prominent. There was no history of bloody discharge from the vagina. A diagnosis of ruptured extra-uterine gestation was confirmed and immediate operation was advised. The patient was wrapped in warm blankets and taken to the theatre, where she was put on a heated operating table and anæsthetised with ether. The skin of the abdomen was then quickly washed and purified and a vertical incision was made above the pubes. When the peritoneum was opened there was a sudden gush of blood and clot. The right appendage was at once seized and clamped, as bleeding was going on, but before it could be brought to the surface it was necessary to detach the Fallopian tube which was firmly adherent to the bottom of Douglas's pouch, the ovary projecting above the tube, to which it was not adherent in any way. On the top of the ovary there was a firm mass surrounded by clot and on lifting this from the ovary a cavity was found in the ovary itself, into which the small ovum would easily fit. The left ovary and tube were examined and were found to be healthy. The mesometrium was then transfixed and the tube and ovary were removed after ligature. For the following description of the specimen, which was now in the museum of the Royal College of Surgeons of England, thanks were due to Mr. S. G. Shattock: "The parts removed are those of an ovarian pregnancy. They comprise the fimbriated end of the right Fallopian tube, the ovary and the ovum partly surrounded by, and embedded in, recent blood-clot. Connected with the fimbriated extremity of the tube are two small pedunculated cysts, the larger about half an inch in diameter. The ostium is crossed by a thin membranous band of adhesion, beneath which a black bristle has been passed. The tube was firmly adherent to the bottom of Douglas's pouch and quite free of the ovary, the highest part of which projected above its level. At the inner pole of the ovary is a partly collapsed cavity about three-quarters of an inch in diameter. This cavity is widely open through a sharply defined semicircular rent of recent origin; in the thin summit of the lid-like portion there is a second narrow, less regular slit half an inch in length. Over the cavity in the ovary lay the lens-like recent clot which is mounted separately in the preparation. The clot is about an inch and a quarter in diameter and of concave-convex form; in its concavity, partly embedded in it and partly free, there lies a villous chorional sac. The sac has been opened in the right half of the clot and the membranes everted; connected with the everted membranes there is displayed a minute embryo about four millimetres in length." From the position of the right tube, the fimbriated extremity of which was firmly fixed to the bottom of the pouch of Douglas, leaving the ovary free above it, it seemed probable that the spermatozoa must have reached the right ovary through the healthy left tube.—The case was discussed by the PRESIDENT and Mr. ALBAN DORAN.

Dr. ARNOLD W. W. LEA showed a rare type of Malignant Ovarian Tumour.

Dr. C. H. J. LOCKYER brought forward a Uterus which showed rapidly growing Epithelioma of the Cervix.

The PRESIDENT and Dr. WILLIAMSON showed specimens of Extra-uterine Gestation.

Dr. A. H. N. LEWERS having demonstrated some sections of Cancer of the Cervix in which from four to 15 years had elapsed without recurrence the subject was discussed by the PRESIDENT, Dr. WILLIAM DUNCAN, Dr. BOXALL, and Mr. MAYO ROBSON.

LARYNGOLOGICAL SOCIETY OF LONDON.

Cancer of the Œsophagus.

A MEETING of this society was held on June 6th, Mr. E. CRESSWELL BABER, the President, being in the chair.

A discussion on the Diagnosis and Treatment of Malignant Stricture of the Œsophagus was opened by Mr. CHARTERS J. SYMONDS whose address we hope to publish shortly.

Dr. HERBERT TILLEY related two cases illustrating the apparent simpleness of the early symptoms in Malignant Œsophageal Stricture. The first case was originally diagnosed as ulcer of the stomach. There was no difficulty in swallowing. On examining the larynx the left vocal cord was found to be paralysed and about three inches down the trachea a small nodular mass projected into its lumen. The patient died from hæmorrhage and on post-mortem examination a malignant ulcer of the lower end of the œsophagus was found. The mass in the trachea was a secondarily infected mediastinal gland. The second case occurred in a man, aged 51 years. He complained of loss of voice and inability to swallow solid food. On examination complete bilateral recurrent paralysis was found. Attempts were made to pass an œsophageal bougie but even the smallest one was arrested opposite the lower end of the manubrium sterni. On further examination a mass of stony hardness was observed in the region of the left lateral lobe of the thyroid. The patient died but no post-mortem examination was made. Dr. Tilley thought that these cases suggested that invaluable information as to the cause of the patient's symptoms might be obtained by the use of the laryngoscope.

Sir FELIX SEMON pointed out the value of the presence of laryngeal paralysis and enlargement of the cervical glands as aids to diagnosis. He thought that alterations in the voice were often present before the ordinary symptoms of malignant disease of the gullet. In cases where the disease affected the posterior aspect of the cricoid cartilage the substance of the crico-arytenoid muscles became affected and caused a myopathic paralysis of one or both of these muscles. This might produce respiratory defects of greater urgency than the difficulty of swallowing. Paralysis might also occur by involvement of the laryngeal nerves when the disease was situated lower in the œsophagus. He considered enlargement of the glands, especially those felt on deep pressure behind the clavicle, to be of diagnostic value. He agreed with the advice which Mr. Symonds had given—namely, in cases where great difficulty was experienced in passing a bougie, to prescribe a night's rest and a dose of opium previously to further attempts. He considered that the dangers of chloroform in these cases should not be underrated and related a case in which unfortunately death had occurred. He thought that functional or spasmodic stricture, apart from organic, certainly occurred.

Dr. E. CLIFFORD BEALE called the society's attention to the possibility of diagnosing growths of the œsophagus by means of the x rays and showed some photographic plates which had been kindly lent to him for the purpose by Dr. Hugh Walsham. He thought that this method of examination gave more information as to the amount of growth and thickening present. Referring to the case related by Mr. Symonds in which a patient, after gastrostomy, had been able to swallow with comfort, he suggested that this good result was produced by rest and freedom from irritation. Other similar cases had been reported and, acting on them, he was then treating a case by getting the patient to swallow hot water after every meal in order to wash the œsophagus and afterwards to swallow a sticky mixture of opium. The result so far had been most satisfactory. He agreed that intra-thoracic disease seldom caused dysphagia.

Mr. H. B. ROBINSON emphasised the importance, which had been pointed out by Sir Felix Semon, of the enlargement of the cervical glands and instanced a case where a mass of glands above the right clavicle had been the first sign which finally led to a diagnosis of stricture of the œsophagus. He also narrated a case of cystic adenoma of the thyroid which had caused dysphagia by pressure which was relieved by operation.

Dr. J. DONELAN related a case of malignant stricture of the œsophagus situated 16 inches from the teeth in which a long bougie had been of great use. Its introduction had been considerably aided by the use of cocaine and he suggested that adrenalin might also be useful.

Dr. J. DUNDAS GRANT related some difficulties which he had experienced in this class of case.

The PRESIDENT doubted the value of œsophagoscopy from a diagnostic point of view and referred to the value of letting a patient sip a solution of cocaine or eucaine before the introduction of bougies. He had not obtained much assistance from the Roentgen rays. As regards anæsthetics in these cases, he could not help thinking there was some peculiar danger. He asked Mr. Symonds if he had had any experience of œsophagectomy in these cases and if he would give a few more particulars about the risks of gastrostomy.

Mr. SYMONDS, in reply, thanked Dr. Tilley and Sir Felix Semon for raising the question of laryngeal paralysis and its value as an early diagnostic sign. He had seen cases where laryngeal paralysis had helped him in the diagnosis, but as a rule he had been able to settle it on other grounds. He could not recall any case where enlargement of the cervical lymphatics had led him to the diagnosis of malignant stricture of the œsophagus and was glad to learn of Mr. Robinson's case. He had had one case of spasm of the sphincter at the lower end of the œsophagus which might be called spasmodic stricture. Replying to Dr. Grant's difficulties he suggested the use of the steel bulb, without which he would certainly have missed many cases. He was interested in Dr. Donelan's case but held strongly that long tubes were inappropriate for disease of the cardiac orifice owing to the many disappointments which he had had. Answering the President as to the danger of gastrostomy he was not prepared at the present time to give a definite reply; if performed at an early stage it should involve very little risk.

DERMATOLOGICAL SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on June 11th, Dr. H. RADCLIFFE CROCKER being in the chair.

Mr. MALCOLM A. MORRIS showed two cases of Bullous Eruption. The first of these was that of a young man, aged 24 years, who had suffered from annual attacks of bullous erythema for many years. The type was that of erythema iris and the present attack was the severest that he *had ever had*. The hands and feet, the extensor surfaces of the knees and elbows, and the mucous membrane of the mouth were all severely affected. The unusual point about the case was the anomalous mode of development, the bullæ appearing first and leaving the infiltrated papules behind on their disappearance, instead of the erythematous papule being the initial lesion, as is the rule. The second case was that of a man, aged 55 years, suffering from Dermatitis Herpetiformis. This was a classical example of the disease of nine months' duration, the supposed cause being mental anxiety from the loss of his situation. The disease had started as a patch of erythema on the left arm and had become multiform and generalised. When shown the arms were the most severely affected, hardly any normal skin being visible, the whole area being covered with erythematous patches, papules, bullæ, and crusts. All treatment had been ineffectual and the disease appeared to be increasing in intensity.

Mr. **WILLMOTT H. EVANS** showed a case of Bullous Eruption, the patient being a woman, aged 39 years. 12 years previously she had taken some quinine and had almost immediately become covered with an erythematous eruption. 10 years previously she had also taken quinine and a bullous eruption had been the result. Now 10 days before admission she had taken what was calculated to be about four grains of quinine in the form of citrate of quinine and iron and the result was the outbreak of an intense erythematous eruption all over the face and arms, with large bullæ of the size of pigeon's eggs on the knees and feet. There was no affection of the mucous membrane of the mouth and the drug had caused no other symptoms than the eruption. The aspect of the patient somewhat suggested renal disease but the exhibitor had not yet been able to obtain a sample of urine for examination.

Dr. **RADCLIFFE CROCKER** showed two cases illustrating different Sequelæ of Vaccination. Both patients were females and both had been vaccinated in October, 1901, with calf lymph. In one of the patients the vaccinia had run an apparently normal course but the healing of the lesions had been accompanied by the formation of hypertrophic scars, so that when shown each of the four lesions appeared as a pinkish, shining, firm, and somewhat dome-shaped swelling, the hypertrophy not extending quite as far as the edge of the scar. The second patient had developed an attack of psoriasis for the first time in her life three weeks before exhibition, the first papules appearing on the sites of vaccination and the spread of the disease having taken place from these situations.—Several members stated that they had recently had under their care similar instances of initial attacks of psoriasis after vaccination.

Dr. **E. G. GRAHAM LITTLE** showed two cases of Tuberculosis of the Skin. The first case was that of a small child, aged two and a half years, who had suffered for 14 months from a small patch of verrucose tuberculosis on the dorsal surface of the right thumb. The patch when shown was of about the size of a sixpenny-piece, raised, horny, and showing on close inspection that soft cushion-like infiltration characteristic of the disease. A point of interest was that two months previously the little patient's father had died from phthisis after a prolonged illness. It was pointed out how likely a child of a little over a year would be to inoculate himself on the hand when crawling about a room undoubtedly containing dust contaminated with the bacillus tuberculosis The second case was that of a child, aged 13 years, suffering from tuberculous adenitis in the neck who exhibited his second attack of the small follicular, acneiform variety of tuberculide. The present eruption affected the extensor surfaces of the arm and legs and the buttocks, and the scars of the previous attack of a year ago were visible upon various parts of the body.

Dr **RADCLIFFE CROCKER** brought forward a case showing the After-effects of the Small Papular Tuberculide of the Face described by Bartelmy as folliculitis. The patient, a young man, had been treated by the application of mercurial plasters with entirely beneficial effects. The resulting scarring was all that remained after this treatment and in time this would flatten down sufficiently to become almost unnoticeable.

Dr. **PRINGLE** showed a case of Lupus Erythematosus. He reminded the members that the patient had been shown before and that the case had been published in the *British Journal of Dermatology* for 1900, p. 1. She had then been affected with multiple patches of epithelioma growing upon an old-standing lupus erythematosus. These growths had been successfully removed by a surgical colleague, but within the last few months a large mass had grown in the region of the right socia parotidis and had lately ulcerated. Further operation did not offer much hopes of success and he would point out that this case was in direct opposition to the view of Holländer that carcinoma on lupus erythematosus was a relatively innocuous form.

Dr. **WHITFIELD** showed a man, aged 30 years, who was suffering from very extensive Lupus Erythematosus of the Face affecting the whole of both cheeks, the bridge of the nose, both ears, several patches on the hairy scalp, and the inside of the lower lip and right cheek. The type was very much infiltrated with a relatively large amount of horny plugging and somewhat deep cribriform scarring. The fingers were also affected to some extent but the great interest of the case lay in a curious violet eruption on the chest and back which took the form of circumscribed infiltrated papules resulting in scarring. These were associated with a certain amount of ordinary acne and the question was whether these lesions were disseminated patches of lupus erythematosus or whether they were tuberculides. The exhibitor held the former opinion which was agreed with by most members present.

Dr. **GRAHAM LITTLE** showed a very classical example of Pityriasis Rubra Pilaris in a child. The face was in the usual diffuse, scaly condition, while the extremities showed the small follicular papules with horny spines and generalised hyperkeratosis. In addition to these there were one or two patches strongly suggestive of psoriasis and it was an interesting fact that a sister of the patient had undoubted psoriasis.

To compare with the above case Dr. **ORMEROD** showed a young woman suffering from extensive Lichen Planus of the Arms and Legs with unusually marked affection of the palms and soles There were among the usual flat lesions on the arms well marked follicular lesions with small spines—the acuminate papules of the disease—and it was pointed out how easily confusion might arise between the two diseases exhibited in the two patients.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.—Intra-peritoneal Rupture of the Bladder —Hæmorrhage into the Spinal Cord during Pregnancy

THE eleventh ordinary meeting of this society was held on June 4th, Professor T. R. FRASER, F.R.S., the President, being in the chair.

Dr **GEORGE GIBSON** showed two patients suffering from Locomotor Ataxia with unusual symptoms The first was that of a man, aged 41 years, who had an isolated paralysis of the internal rectus muscle of the left eye; there were no Argyll-Robertson phenomena or changes in the optic disc; the patient was subject to curious attacks of delirium. The second case was that of a man with few ataxic phenomena but with absolute atrophy of the optic nerve of the left eye and also the same in the right side to a great degree. He also showed peculiar twitching movements of the skeletal muscles.

Mr. **F. M. CAIRD** showed a male patient in whom he had performed double enterectomy for Tuberculous Stricture of the Small Intestine at one *séance*. The patient had suffered for six or seven years from gastric symptoms—pain and vomiting after eating Diarrhœa had commenced 14 days previously to the operation. He was greatly emaciated and suffered constant pain. Nothing abnormal could be felt in the abdomen but the diagnosis was made of tuberculous stricture.

Dr **WILLIAM ELDER** exhibited a boy who had suffered from Choreiform Movements since he had scarlet fever five years previously During convalescence from this exanthem movements began to show themselves in the facial and oral muscles. These movements had gradually spread to other parts of the body. A peculiar distressing grunting noise was produced involuntarily by the contraction of the intercostal muscles. At times, as during service in church, he could control these motions, as also when making any voluntary efforts, as in holding his knife and fork or raising a cup. Intellectually he was correct but at times expletives escaped involuntarily. Dr. Elder rather thought that this was a case of paramyoclonus multiplex and not a case of chronic chorea (Sydenham).

Mr. **H. ALEXIS THOMSON** exhibited a patient after laparotomy for Purulent Peritonitis of Gonorrhœal Origin and Removal of the Left Ovary and Fallopian Tube. The disease developed five weeks post partum. A second laparotomy had to be performed 10 weeks after the first on account of acute intestinal obstruction due to at least six constricting adhesion bands.

Mr. F. M. Graham showed the Base of a Skull in which there was absence of the Right Lateral Sinus, &c.

Mr. Caird showed an Intestine in which there was a Double Tuberculous Stricture.

Dr. Harvey Littlejohn showed: (1) specimens illustrating Compression of the Brain from hæmorrhage; (2) specimens illustrating the effect produced on the hands and feet by prolonged immersion in water; (3) *a*, Uterus showing appearance in Menstruation and *b*, Uterus from a case of Abortion at the Fifth Month resulting from External Violence; and (4) Photographs of a case of Drowning.

Mr. Shaw M'Laren read a paper on Intra-peritoneal Rupture of the Bladder with notes of two cases, one of which recovered after suture. He began by noting the comparative rarity of the accident. Rivington was able to record only about 190 cases in all. Recovery from the accident was a still rarer event. Alexander of New York in a paper published last year gave a list of 23 recoveries, in all of which the bladder was sutured. As regards the cause of rupture, blows on the abdomen containing a distended bladder, the crushing of a cart wheel, falls from a height, &c., were common. In Mr. M'Laren's second case the rupture followed on a simple fall on the abdomen, not from a height, but while the patient was ascending a stair. Mr. M'Laren did not think that it was proved that the accident could not occur but to a fully distended bladder (that was, when the pelvis was not broken). Several cases seemed to throw doubt on this generally accepted condition, notably one where it was stated that a man was thrown from a dogcart and sustained a rupture of the bladder half an hour after he had emptied it. This the patient was certain of and even though he had been drinking fairly freely, alcohol could scarcely be capable of producing so pronounced a diuresis as to fill the bladder to distension within half an hour. It must, however, be remembered that the "tone" of the bladder varied apparently at different times; in certain circumstances the demand for urination was urgent though the bladder contained only a small quantity of fluid, while at another time it might have collected a large quantity and yet its walls be lax enough to require further distension before micturition was called for. The rent was usually vertical; in only eight out of 110 cases was it transverse. There was one site where it occurred by far most frequently —viz., the posterior superior aspect of the bladder. Rivington explained this by stating that the lower part of the bladder was supported by the pelvis, while the upper part was surrounded merely by the yielding intestines and so the fluid escaped from this area when the bladder was crushed. Alexander held with others that the bladder was driven up against the sacral promontory and ruptured at this point. It was difficult to understand this from a study of frozen sections and, even if it were driven up, how the transverse projection of the bone could produce in almost every case a vertical rent. It was possible that the disposition of the muscular fibres of the bladder wall had not been sufficiently considered in this regard. There were three muscular layers in the bladder, two being disposed longitudinally and one circularly. This middle circular layer was not the strongest and its upper fibres tended to assume the longitudinal direction. In fact, the circular fibres were strong only in the lower and extra-peritoneal portion. The upper and back part of the vesical wall thus mainly consisted of longitudinal fibres and pressure on the contained urine would tend to drive it through between these strands. This would explain both the situation and the direction of the rupture. The symptoms were well known —shock, vomiting, inability to stand, hypogastric pain, urgent desire to urinate with inability to do so, bloody urine, and certain peculiarities in catheterisation. Shock was frequently, however, absent and in some cases the patient was able to stand, but in few could he stand upright. Desire to urinate might be wanting on account of alcoholic intoxication in the early stages and in the later from uræmic intoxication. Pain and tenderness in the hypogastric region Mr. M'Laren regarded as extremely important symptoms. He had found them present in all cases of rupture he had met with, both intra- and extra-peritoneal. The absence of this symptom must not, however, allow one to be misled. One symptom which Mr. M'Laren had not seen recorded was related by the first patient he treated: this was that as the cart passed over his abdomen urine squirted from his penis. The chief symptom was failure on attempting to urinate and on passing the catheter merely a few drops of bloody urine were obtained. This "bloody anuria" (*blutigo anurie* of Rose) was most striking and characteristic and occurring after an injury to the abdomen it almost sufficed for a diagnosis. The catheter drew off only a few drops of bloody urine and found itself in a contracted bladder which permitted no movement of its point and only rarely did it pass through the rent in the bladder. In the latter case it might give exit to large quantities of urine almost or quite free from blood, especially in the later stages. Mr. M'Laren thought that the injection and inflation tests were useless; all the fluid injected might return though there was a rent in the bladder, and inflation test was really dangerous. Cases difficult of diagnosis occurred, as when the patient was able to walk after the accident, or even continued well for some days either urinating normally or through a catheter. The symptom of bloody anuria might possibly seem to point to contusion of the kidney or rupture of the urethra. In the first case, however, the bloody urine was normal in amount and there was great tenderness on pressure over the loins, while in the second there was a spontaneous flow of blood from the urethra and if urine was retained the bladder dulness was easily recognised. The cause of death after rupture was either peritonitis or uræmic intoxication. Why should septic peritonitis arise? It had been often proved that aseptic urine could be introduced into the peritoneal cavity without injury. In many cases where peritonitis was the cause of death the urine was normal. On the other hand, organisms could pass through the intestinal wall even though it was unruptured provided that the tissues of the wall were damaged. It was possible that the bruising of the intestines which must result from the blow which ruptured the bladder might permit the passage of organisms through its wall and so infect the extravasated urine. As regards treatment, this consisted in opening the peritoneal cavity and suturing the rent in the bladder wall. Should the mucous membrane be sutured as well as the other layers? Most surgeons merely passed one or two rows of Lembert's sutures through the muscular and peritoneal layers. Mr. M'Laren sutured the mucous membrane in his first case but he had only found one other surgeon (Mikulicz) who did so; catgut sutures, of course, must be employed. Except in a few cases a tube should always be left in the pouch of Douglas because they had to deal with a damaged peritoneum and bruised viscera. Mr. M'Laren also thought it was better not to tie in a catheter to drain the bladder but that it should be passed once every two to four hours for the first one or two days. In every case the bladder should be emptied by the catheter at the end of the operation. The notes of the two cases were as follows. Case 1.—The patient was a van driver, aged 33 years. A wheel had passed over his abdomen. There was inability to urinate. There was no collapse. He had swelling in the right hypogastric and umbilical regions. At the operation a vertical fairly clean cut rent from three to four inches long on the postero-superior aspect was found. The mucous membrane was stitched separately and then two rows of Lembert sutures were inserted. There was prolonged washing of the peritoneal cavity. Complete recovery ensued. Case 2.—The patient was a tailor, aged 45 years. While intoxicated he fell on the steps of a stair. At the operation large quantities of blood-clot were removed from the abdomen. There was a very ragged rent three inches long on the postero-superior aspect of the bladder. There was great prostration after the operation but the patient rallied when five pints of hot saline fluid had been injected into the median basilic vein. He urinated normally in two days. On the fourth day, however, symptoms of delirium tremens developed and he died six days after operation. Pelvic peritonitis was present at the sectio—slight leakage from the posterior sutures was found. In all, 23 recoveries were recorded and Mr. M'Laren's made the twenty-fourth.—Mr. Caird, Dr. A. Miles, Dr. Harvey Littlejohn, and Mr. Alexis Thomson took part in the discussion which followed.

Dr. Alexander Bruce read notes of a case of Hæmorrhage into the Spinal Cord in a Pregnant Woman. The symptoms were sudden onset with acute tearing pain in the mid-dorsal region, extending into the extremities; complete and permanently flaccid paralysis of the lower extremities, abdominal walls, bladder and rectal sphincters; early abolition and subsequently slight return of deep reflexes;

occurred and that contamination, although on a comparatively minute scale, during continuance of supply is probable. Chemical analysis of the water, and still more microscopical examination, afford important confirmatory results. Dr. Dupré, to whom samples were sent for analysis, reports that water taken from a house tap in Henry-street *before the nightly intermission of service* was pure, while that from the same tap after intermission gives evidence of animal contamination and of the appearance of low forms of life. Water from a tap in Victoria-street (Miskin) shows similar deterioration both in the night and morning supplies."

An interesting case at Buckingham in 1888 was reported upon by Dr. Franklin Parsons. There was a sudden outbreak of typhoid fever in that town in January and February, 1888, confined at first to a poor suburb of the town, and especially affecting persons drinking water from a particular "spout." "The water conduit to this spout was exposed to pollution from a leaky drain which had received specifically infected excreta from a previous case of enteric fever."

An outbreak of typhoid fever at Fareham (Hants) was reported by Mr. Spear in 1888 to have been traced by the medical officer of health "to pollution of an intermittent water-supply through numerous direct connexions between the water mains and the pans of water-closets. After this was remedied and a constant supply of water afforded enteric fever became less prevalent in the town." Mr. Spear also reported in the same year that an outbreak had taken place in Flint, where the water-supply was intermittent and where in the specially infected locality there was an "allegation of discolouration of the water when turned on in the morning" In 1889 Mr Spear reported that at Strood and Rochester, where typhoid fever had been prevalent, he "found water-closets supplied direct from the mains—i.e., without the intervention of any cistern or tank. The danger of insuction of air and even of solid matter into the water-pipes from closet-pans during any temporary disconnexion of water-pressure is well known to attend this objectionable arrangement."

Dr. Wheaton reported in 1893 on an outbreak which was almost entirely confined to a limited area in the town of Atherstone (Warwick). The "outbreak was not due to excrement disposal, sewerage, drainage, or milk-supply; *but to the introduction nightly into the town water mains for a period of eight weeks of an extraneous water-supply which was subject to pollution*. The localisation of the fever outbreak was explained by the peculiar distribution of the water mains owing to which the suspected water was almost entirely consumed within the area to which the fever in question was almost entirely confined. The prevalence of the disease was in part due to infection from the privy-middens, also to contamination of water-supply by a residue of suspected water remaining in the mains and continued consumption of the same water, which was obtained from a public tap."

In 1899 Dr. G S Buchanan reported with regard to a serious outbreak at Falmouth (Cornwall) that there were "reasons for inferring that insuction of infectious matter into Falmouth water mains during periods of intermission of supply had concern with the epidemic." The water-pipe, in which there was a roughly made and leaky joint, was laid underneath the stones of a yard where the soil was "everywhere black and impregnated with foul organic matter" This was caused by the leaky drain and a water-closet down which typhoid excreta had been thrown, and Dr Buchanan proved by a test that suction into this main actually did take place under certain circumstances.

There are very few instances in which sewage irrigation on land has been shown to be the cause of typhoid fever It is indeed a remarkable fact that typhoid fever does not occur among the employés on sewage farms, even when they drink the water of wells on the farm, which is frequently the case. In some few instances, however, owing to mismanagement of some kind or other, outbreaks of typhoid fever have occurred in connexion with sewage irrigation. One was the outbreak at Beverley in 1884 already referred to.

We now come to the *distribution of the disease by means of infected milk*. In 1862 an investigation was made by Professor John Gamgee on Cattle Disease in Relation to the Supply of Meat and Milk and his report was published in the fifth report of the medical officer of the Privy Council. He came to the conclusion "that the cause at present operating most actively to deteriorate the milk of cows in this country is the prevalence of epizoötic aphtha. This disease attacks the human subject and many cases of communication from cattle to man have been observed either from the virus penetrating a wound or passing into the system with the milk." Sir John Simon adds to this: "Experiment seems to have established as certain that, at least under some circumstances, the human affection may be caused by the consumption of milk drawn from a diseased animal." And it is in a footnote that "more than 20 years ago Professor Hertwig published particulars of such experiments performed by him on himself and two friends with the result of producing a very definite eruptive fever."

Dr. Edward Ballard, when medical officer of health of Islington, first traced an outbreak of typhoid fever through milk supply in 1870 This investigation is so important that I insert the following lengthy quotations from his report: "The general result of an inquiry into the milk-supply of the families within the quarter-mile radius into which I ascertained that typhoid fever had entered was this—viz.: That it occurred in the house of the milk vendor where the business, was carried on. He died and seven other persons, members of his family or boys employed and living on the premises, had typhoid fever and one of the latter died. That it occurred in the family of a person who dwelt in a small cottage in the cowyard distant about 100 yards from the last-mentioned house and dairy, three persons having fever here. The first case here was in a girl, who, a fortnight before she actually fell ill, had left a situation at a public-house supplied with milk from this dairy and since then had been residing at home. This family, the mother of the girl told me, rarely took milk, except on Sundays, being poor, but when the girl was ill milk was given to them from the dairy The mother herself, and subsequently a little boy, had typhoid fever when the girl was convalescent. That, in addition to the two boys who had lived in the house for a longer or shorter time, two men engaged in the business who did not live in the house had typhoid fever. One of these was the cowman engaged after the master was taken ill; the other was a young man who worked at the cowyard and carried out milk and who took all his meals at a coffee-shop supplied from the dairy and where two families also supplied from the dairy had fever. That a fifth man employed at the cowyard and residing at home had fever. He also occasionally had his meals at the above mentioned coffee shop and his tea at his mother's who was supplied from the dairy His family being poor he bought no milk for them anywhere and he was the only member of it attacked. That another single man residing within the radius in a wholesome house and engaged as a coachman outside the radius, who habitually took his meals at this same coffee-house, had an attack of typhoid fever. That (omitting the girl who came ill from the country) out of 62 other families within the district which are known to have suffered from typhoid fever, 54, or fully 87 per cent., were constantly supplied from the dairy with the milk they required, two were occasional customers, and five only stated that they did not deal there at all. I am not quite sure that complete reliance can be placed on this last statement; certainly I doubt it in one case of the five. All five resided close to the dairy and it is very probable obtained there, as the most convenient place, any extra milk their families required. In another instance a girl was attacked in a family not supplied by the dairy, but it appeared that on two consecutive days in the beginning of July she had taken tea with a schoolfellow who, with her mother, had typhoid fever a few days later, this family being supplied from the dairy. No one else in this girl's family had fever."

On inquiring into the fatal cases happening in families residing in the quarter-mile radius from the dairy he found, "That the members of 142 families were supplied with milk from the dairy in question. The district within the quarter-mile radius alone must contain over 2000 families. So, after all, no very considerable proportion got their supply from this source. Out of these 143 families (which include the dairyman's household) I have ascertained that 70 were invaded by typhoid fever within the 10 weeks during which the outbreak extended—that is to say, half of them were invaded. This includes all the families which had deaths from typhoid fever" On searching for the cause of the contamination Dr Ballard found that it came from an underground wooden tank constructed 16 years before which had become rotten and was found to communicate with two old drains by means of rat-burrows in such a manner that not only foul air from the drains but also an overflow of sewage slight dorsiflexion of the great toe on tickling the soles, rapid formation of sacral and gluteal bed sores, painless and unconscious delivery of twins, with temporary relief to previous embarrassment of respiration, subsequent development of bronchitis, and sinking from exhaustion. Post-mortem examination showed a tubular hæmorrhage, mainly in the lower half of the dorsal region and occupying the grey matter, pushing the white substance aside without completely interrupting its continuity In the upper dorsal and lower cervical region the grey matter was infiltrated with blood but to a much less extent. In the lower dorsal region a tubular structure with thick walls evidently due to irregular closure of the central canal, was filled with blood which had ruptured into it. The source of the hæmorrhage was evidently an angio-glioma in the grey matter There were several similar small angio-gliomata in the dorsal region under the membranes and in the white matter, and one larger in the postero-lateral columns at the level of the fifth cervical segment. The paper was illustrated by lantern slides showing the seat and distribution of the above mentioned morbid appearances. Dr Bruce discussed the etiology and pathology of hæmatomyelia and also referred to Dr Amand Routh's paper on parturition in cases of paraplegia from lesions at various levels of the cord —Dr GEORGE A GIBSON related a case of Sudden Onset of Complete Paraplegia in a woman, aged 47 years. The right mamma had been removed on account of carcinoma. It was therefore thought that the lesion in the cord was due to such a new growth there or that it was a case of acute transverse myelitis The case was under observation for several months so that it was not likely to have been a hæmatomyelia. After death a fracture of the sixth dorsal vertebra was found This had not been noted at the time of the onset of the paraplegia. Dr Gibson thought that it was remarkable that Dr. Bruce's patient should have exhibited no phenomena due to the lesion in the cord prior to the onset of the hæmorrhage.—Dr C E. UNDERHILL and the PRESIDENT having spoken, Dr BRUCE replied.

EDINBURGH OBSTETRICAL SOCIETY

Exhibition of Specimens —Epithelioma of the Vulva — Repeated Ovariotomy —The Use and Abuse of the Forceps

A MEETING of this society was held on June 11th, Dr JAMES RITCHIE, the President, being in the chair

Specimens were exhibited by Professor A R. SIMPSON, Dr D BERRY HART Dr J HAIG FERGUSON, and Dr W FORDYCE.

Dr D A. CALLENDER read notes on a case of Epithelioma of the Vulva. The growth was removed but in six weeks there was recurrence and a second operation was carried out there was, however, rapid advance of the disease with discharge of a large quantity of thin serous fluid The x rays had recently been employed and after four applications the discharge had become much less, the pain had greatly abated and the general health had improved.

Professor J A C KYNOCH (Dundee) read a paper on Repeated Ovariotomy Repeated ovariotomy raised the interesting question, What was to be done with the apparently healthy ovary in cases of operation for unilateral cystic disease? The exact clinical significance of papillomatous growths was a disputed question but the researches of Pfannenstiel and Williams had done much to show their true character The former had shown that papillomatous growths might be associated with perfectly simple ovarian cysts causing implantation and metastasis on the peritoneum with ascites, and yet the condition might be permanently cured in many cases on the removal of the tumour On the other hand he found that one half of the cystic carcinomata of the ovary were papillary in nature and gave rise to true metastasis in the glands, the liver and other organs. It was therefore in the case of papillary cysts that the removal, partial or complete, of the other ovary was of most importance because it was difficult or impossible during the course of an operation to say with any degree of certainty whether they were dealing with a simple or malignant papillomatous tumour The operator should inform the patient before operation that the other ovary might at the same time have to be removed. This was especially necessary during the child bearing period. In women at or about the climacteric it would probably be a safe rule to remove the unaffected ovary in every case. In younger patients they had to consider the relative advantages of leaving the ovary, of partially excising it, or of removing it altogether By leaving the ovary the absence of the distressing symptoms of an artificial menopause and the possibility of a subsequent pregnancy must be contrasted with the slight risk which the patient ran of a repeated ovariotomy According to the statistics of Spencer Wells only in 2·6 per cent. of unilateral ovariotomies was the repeated operation necessary and of 228 ovariotomies 120 of the patients subsequently bore children If patients could be kept under observation after operation so that early manifestation of recurrence could be detected there would not be the same danger in leaving the unaffected ovary But in the case of papillomatous tumours the recurrent growth spread so rapidly that by the time the patients came under observation operation was frequently useless When the other ovary showed incipient disease simple puncture with the knife or cautery might be sufficient. Of 10 cases treated thus by Martin during the course of an unilateral ovariotomy three of the patients subsequently became pregnant and in no case was a second operation required for recurrent cystic disease In small œdematous and dermoid cysts resection of the ovary had the advantage in younger patients of probably removing the disease and at the same time leaving sufficient ovarian tissue to permit of ovulation and subsequent pregnancy Mathai reported from Olshausen's Klinik six cases of pregnancy following partial resection of dermoid cysts. Mere resection of a papillary cyst was not safe, such a case of recurrence was reported by Odebman Pfannenstiel wrote that in all cases of papillomatous, sarcomatous or carcinomatous tumours of the ovary the other ovary must be removed at the same time, and in all forms of tumour the other ovary should always be removed in patients over 40 years of age. Professor Kynoch then gave detailed reports of three cases of recurrence in his practice. One was a multilocular cyst recurring in two and a half years in the other ovary, in another an ovarian cyst chiefly unilocular was followed by a unilocular papillomatous cyst in the other ovary 15 months afterwards, and in the third an apparently simple multilocular cyst was followed in nine months by a second ovariotomy when nodules were also found scattered over the peritoneum.—Dr HART Dr F W N HAULTAIN Dr J LAMOND LACKIE, Dr FERGUSON, and Dr J W BALLANTYNE discussed the paper and Professor KYNOCH replied.

Dr MICHAEL DEWAR read a paper on the Use and Abuse of Forceps in General Practice. Reference was made to discussions on the subject at the medical congresses at Montreal in 1897 and at Edinburgh in 1898. Most of the speaking on those occasions came from men who were engaged in hospital and high-class practice. Much was said about the great dangers attending the use of forceps to mother and child, but very few facts were given which showed the percentage of injuries said to be due to the use of forceps. In obstetric practice everyone must or ought to be an expert and in many cases the practical training during the student curriculum was very deficient. Dr W J Sinclair of Manchester five years ago had made a vigorous onslaught on the too great frequency with which forceps were used in practice and had urged that anything above from 3 to 5 per cent of forceps cases was unnecessary Others admitted that from 12 to 15 per cent was a fair average In making an estimate discrimination should be exercised as to whether the cases occurred in city or country practice In the city the patients were often more or less anæmic poorly developed, and often with some contraction of the conjugate which though slight, would yet be sufficient to cause a difficult labour By intercommunication the city woman had learned to be less patient and many among the working classes demanded the help of chloroform and forceps soon after the arrival of the medical attendant. Among the higher classes there was more self control and a well trained nurse helped to calm the fears of the patient so that there was not the same importunity for assistance If a woman was in hospital then she was surrounded by a discipline which compelled her to wait till the obstetrician thought it necessary to interfere, that no doubt accounted for the small percentage of forceps cases in hospital In the country the women were more robust and owing to the greater segregation and the distance of their residences from that of their medical attendants they were taught to endure pain of all kinds more heroically Many country women had a horror of the 'irons, as they were called and only when quite exhausted would they permit assistance to be given. The percentage of forceps cases was thus very much smaller in the country than in the town. 30 years ago the percentage of forceps cases in the Edinburgh Maternity Hospital was 0·21, with a maternal mortality of 0 8 per cent. In the Dresden Hospital from 1883 to 1888 the percentage was 2 8, with a maternal mortality of 3·4 per cent. and an infantile mortality of 17 per cent. Recently the percentage in the Edinburgh Maternity Hospital was 10 6 per cent., with a maternal mortality of 1·3 per cent. and an infantile mortality of 4 per cent., while in the extern practice the percentage of forceps cases was 4·3 per cent., with a maternal mortality of 0 4 per cent. and an infantile mortality of 11 per cent. Several obstetricians maintained that 5 per cent. should never be exceeded, which might be correct and proper under the best conditions but which would be impossible to carry out in a working-class practice. Dr. Dewar stated that while he was in country practice from 1877 to 1881 he used forceps in 11 per cent. out of 700 cases; of this series the percentage in primiparæ was 20. Other medical men in the country had given their forceps cases as 10 per cent., 12 5 per cent., 13 per cent., 30 per cent., and 10 per cent. These numbers might be taken as the fair average in careful midwifery in the country. In his city experience of 300 cases Dr. Dewar applied forceps in 35 per cent., and he found the percentage of six other practitioners to be 35, 38, 39, 40, 45, and one of 10, but he stated that it had been 20 a few years ago. Regarding the maternal mortality Dr. Dewar had no death after forceps in his 700 cases in the country; among the children there were 20 deaths, or a percentage of 2 8. In his series of 300 city cases there was no death after forceps—indeed, only one in the whole number, from heart disease. Two infants died in the instrumental cases, or a mortality of 1·9 per cent. for forceps. Dr. Dewar also considered the mortality and the period of convalescence of the different classes of cases.—The paper was discussed by Dr. S. MacVie, Dr. G. Keppie Paterson, Dr. Haultain, Dr. Ferguson, Dr. Hart, Dr. Ballantyne, and Professor Kynoch, and Dr. Dewar replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Obstetrics.

First Stage of Labour.—Exhibition of Specimens.

A meeting of this section was held on May 23rd, Dr. W. J. Smyly being in the chair.

Mr. E. Hastings Tweedy read a paper entitled "Observations on the First Stage of Labour: the Causal Relation of this Stage to Rupture of the Uterus." He said that the onset of labour ought to be reckoned from the moment of the establishment of uterine polarity. Uterine polarity was probably induced by an over-stretched condition of the lower uterine segment nerves brought about as a result of labour contractions. A fully dilated os was not always of a diameter sufficient to permit of the passage of the fœtus. The condition known as rigid os, with its thin knife like edge, was in reality an os that had reached its maximum degree of expansion. In primiparæ especially an os in this state was readily torn, but in the event of its not quickly doing so it moved in a direction upward and backward in response to the more powerful pull exerted on it by the posterior uterine muscular fibres. In consequence of this the anterior cervical lip became enormously elongated and was erroneously spoken of as being incarcerated or nipped between the os pubis and the presenting part of the fœtus. The liberation of the lip necessitated the tearing of the cervix. A lip such as this became rapidly œdematous and often protruded through the vulva at the completion of labour. Under these circumstances the cervical rent, though extensive, could not be dealt with by immediate suture, not alone because of the great œdema but chiefly for the reason that there was never any posterior lip to which to stitch it. Occasionally the os did not tear after it had moved upward and backward. Then rupture of the lower uterine segment and of the anterior fornix of the vagina became probable. These structures would, under the conditions named, lie one on the top of the other and would be subjected to the counter pulls of anterior and posterior uterine fibres. Ruptures such as these took place insidiously, the only symptom which marked their onset being the moving of the rigid os upward and backward—Dr. A. J. Horne said that in his experience cases of ruptured uterus were usually associated with contracted pelves and were consequently unusual in Dublin where the condition named was seldom met with. He did not look on the strong pains as the principal cause: he rather inclined to the idea that insufficient dilatation or dilatation slowly occurring was the chief factor, the head being suddenly forced through rather than pressed through.—Dr. Alfred J. Smith said that he did not see much benefit from Mr. Tweedy's new definition. "Polarity" was hardly a practical term. The old definition of the beginning of labour was equal to all demands.—Dr. Henry Jellett said that he did not accept Mr. Tweedy's explanation of polarity; he associated it more with some regulating nerve-fibres connected with the higher nerve centres which regulated the muscular contractions in a manner analogous to the simultaneous contractions of the fibres of the body and relaxation of the sphincter of the bladder and the rectum. In his opinion the first stage of labour ended clinically with rupture of the membranes.—Dr. Smyly said that Mr. Tweedy's paper dealt with two subjects—the first stage of labour and rupture of the uterus. Much depended on where he considered the polarity to begin; if he included the whole lower uterine segment the labour might be said to commence at the seventh month of pregnancy.—Mr. Tweedy, in replying, said that he did not see that any analogy could properly be drawn between the bladder mechanism connected with urination and that of the uterus in the first stage of labour. The formation of the lower uterine segment during pregnancy caused considerable displacement of the vessels and nerves, as these had to course through this segment in order to reach the cervix. In consequence of this the relaxation of the os during the period of a labour contraction could be accounted for in a manner more simple than by inferring a special nerve centre which had so rarely to be called into existence.

Dr. Smith exhibited two specimens of Double Pyosalpinx of Tuberculous Origin. The first consisted of tubes removed from a patient, aged 19 years, who had suffered from amenorrhœa for one year previously; the second consisted of tubes from a patient, aged 35 years, who had suffered from dysmenorrhœa with profuse menstrual flow. He also exhibited a large Pyosalpinx removed from the left side of a married woman who was anxious to become pregnant. In the latter case the right tube and ovary were apparently normal; the enlarged tube was intimately adherent and very tense and its contents showed tuberculous deposits and pure cultures of staphylococci. This was interesting as there was no history of the invasion and the right tube and ovary were normal.

Dr. Horne exhibited a Uterus removed by Vaginal Hysterectomy. The patient was 50 years of age and was the mother of two children, her last pregnancy having taken place nine years previously. Menstruation remained regular until a year previously, when it ceased for three months and then became irregular. On examination the uterus was found to be freely moveable and in its normal position. There had been no watery discharge. Curettage of the uterus was performed to check the hæmorrhage. On examination of scrapings from the uterus Professor E. J. McWeeney reported:—"These are very succulent, richly cellular, and exhibit an adenomatous overgrowth of the uterine glands which appears to be undergoing malignant change, is in fact partly converted into adeno-carcinoma." Vaginal hysterectomy was thereupon performed. The convalescence was perfectly normal. The important points which he wished to call attention to were the absence of the usual symptoms associated with malignant disease, and the importance of having uterine scrapings carefully examined by the microscope in women near the climacteric when menstruation was irregular.

Bradford Medico-Chirurgical Society.—A meeting of this society was held on May 27th, Dr. H. J. Campbell being in the chair.—Dr. F. W. Eurich gave a microscopical demonstration of (1) specimens showing Calcification of Arteries, Nerve Cells, and Capillaries in the Brain; and (2) Sputum containing an Aspergillus which was thought to have been the primary cause of the pulmonary disease.—Dr. W. Mitchell exhibited the cast of a Hand showing a Supernumerary Thumb.—Dr. J. H. Bell read a paper on Pulsating Exophthalmos. After reviewing the history of the disease and of its treatment and pointing out its great rarity Dr. Bell related the following case. The patient was a man, aged 29 years, who was admitted to the Bradford Eye and Ear Hospital in July, 1896, complaining of prominence of the right eye together with a loud buzzing noise in the head. Ten days previously he had received a blow on the left eye during a drunken brawl. The next day on awaking he heard a loud noise in his head; the left eyelids were black and the right eyelids were not so. For some days there was vomiting and headache due probably to the drink which he had taken. The right eye then became prominent and he had diplopia for about a week. There was no history of syphilis. Examination showed the right eye to be prominent and there was paresis of the superior, inferior, and internal recti muscles. The vision of both eyes was equal to average normal. Ophthalmoscopical examination was negative. He worked for a week and said that his eye got fairly well and he then became ill with weakness and vomiting and had to go to bed and the eye became worse. He was then taken as an in-patient at the hospital. The right eye-ball was displaced downwards, outwards, and forwards. Pulsation developed and a loud bruit was heard with the stethoscope all over the head. The bruit was lessened by pressure on the right common carotid artery and was stopped by pressure on the left common carotid. The heart sounds were clear; the urine was normal. The ophthalmoscope showed fulness of vessels in the fundus but no pulsation and no papillitis. Digital compression by the patient was commenced on the left side and after a week was changed to the right side. It was carried on for two minutes hourly during the day and for one minute hourly during the night without causing much pain. After three weeks the vision was normal, the bruit remaining as before. From Oct. 14th Carte's tourniquet was applied daily for five months, averaging four or five hours a day. In February the noise occasionally stopped and the bruit sometimes could not be heard. On March 4th, 1897, the left common carotid was tied. The bruit at once ceased but had returned by the time that the patient had been put to bed. On the following day the bruit was heard faintly at the vertex, then for 19 days no bruit could be heard, but it returned on March 24th, though it was not so loud as before. On April 21st the man was made an out-patient. On May 11th he was re-admitted, the vision of the fundus oculi and the noise in the head being the same as they were before. Compression by means of Carte's tourniquet of the right common carotid was now practised daily but without any result as regarded the symptoms. On July 22nd the right common carotid was tied. The bruit ceased and there was no pulsation in the temporal artery. On the next day the patient was drowsy, with slow cerebration, there was no bruit, and the pulsation had returned in the temporal artery. On the 24th he became hemiplegic on the left side, with hemianæsthesia. There were chronic and tonic spasms of the right side. He died on the next day. The necropsy showed softening of the right cerebral hemisphere. The vessels at the base were normal. The right cavernous sinus was dilated but no further abnormality was detected. In his remarks on the case Dr. Bell said that the following points were of interest: (1) the blow was on the left eye and the exophthalmos was on the right side; (2) the vision was practically normal throughout; (3) the bruit was controlled by pressure on the opposite carotid artery; and (4) the patient was able to bear such long-continued compressions of the arteries without suffering much discomfort.—Dr. S. Lodge, jun., read the notes of a case of Tuberculous Tumour of the Middle Lobe of the Cerebellum which ended in sudden death. The brain from the case was shown.—Mr. J. Phillips made some remarks on the Treatment of Burns. He advocated the use of gauze soaked in 10 per cent. eucalyptus oil. He said that burns treated in this way did not require such frequent dressing as when ointments were used and further that the discharges could soak through and be taken up by an outer layer of some absorbent material, thus preventing the healing surface from being constantly bathed in pus.—Dr. A. Bronner made remarks on the Use of the Electro-magnate in Ophthalmic Surgery. He advocated the use of very powerful magnets and described some of these instruments together with the methods of their employment.

BRITISH GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on June 12th, Dr. Heywood Smith, a vice-president, being in the chair.—The President, Dr. J. Halliday Croom, had sent for the consideration of the Fellows the following two specimens: 1. A Uterus removed for disease diagnosed from microscopical examination to be malignant but proving to be only recrudescing fibroid. His note suggested that similar cases might account for some alleged cures of cancer by hysterectomy. 2. A Uterus and Placenta removed after delivery of a living child by Cæsarean section on account of a large fibroid obstructing labour.—Dr. H. Macnaughton-Jones read notes of a case of Albuminuria in which early in the seventh month without rupture of the membrane or any laceration of the cervix he had in 20 minutes effected dilatation by means of Professor Bossi's instrument.[1]—Dr. Heywood Smith showed Kurz's Suture Forceps, one blade of which acted as needle-holder; the other, on closing the instrument, seized the threaded needle and, when the blades were separated, withdrew it.—In a paper entitled, "Is there any Real Deciduoma Malignum" Dr. Herbert Snow questioned whether the malignant developments immediately following and often unmistakeably due to the trauma of parturition showed any title to a special term differentiating them from cancerous new growths in or about the uterus apart from gestation. Micro-photographs Dr. Snow considered misleading where malignant cell-growth was concerned; a conscientious drawing might convey the truth, but a micro-photograph could not do so. Clinically, the lesions in no way differed from those of uterine carcinoma, sarcoma, or myosarcoma of the uterus under the increased vascular tension of pregnancy. Even in the most acute forms of cancer some time was required for the development of widely sundered metastases, and from what they knew of malignant disease elsewhere it was highly improbable that the extensive lesions met with in many cases could have commenced during pregnancy, as cancer was never set up while healthy cell-proliferation was going on. The only inference to be drawn was that the malignant development began before conception and that the phenomena of cancer of the uterine body, always obscure and insidious, were masked by the pregnancy. The only valid treatment was complete hysterectomy.—Dr. Heywood Smith was inclined to attribute greater value to micro-photographs than Dr. Snow attributed to them; a drawing was done with a certain amount of bias and might accentuate points that a photograph would represent with greater truth. If the disease originated in the decidua a theoretical distinction might be drawn between it and malignancy arising in the wall of the uterus. Many patients seemed to have lost ground very rapidly after the use of the curette.—Dr. Macnaughton-Jones held that practically they must recognise deciduoma malignum as a malignant disease connected with the products of conception, with characteristic profuse hæmorrhage and tendency to necrosis. Whether it approached carcinoma or sarcoma in character was of little importance compared with its early recognition and prompt extirpation.—Dr. J. J. Macan pointed out that widely as Veit differed from Marchand as to the nature of the disease they entirely agreed as to its clinical aspects and all its essential microscopical characteristics. In view of the number of recorded cases it seemed idle to deny the existence of a peculiar form of malignant disease intimately connected with pregnancy for which, out of the dozen or score of names that had been given to it, "chorio-epithelioma malignum," the one suggested some years ago by Marchand, was now most generally acceptable.

---

[1] THE LANCET, March 1st, 1902, p. 591.

AFFILIATED BENEFIT NURSING ASSOCIATIONS.—The ninth annual conference of the Affiliated Benefit Nursing Associations for the supply of cottage nurses on the Holt-Ockley system was held on June 13th at 68, Ennismore-gardens, S.W. Lord Ancaster, who presided, said that during the past year the associations had made great progress and had met with considerable success. There was great difficulty in getting sufficient nurses to supply the demand. Miss Broadwood, the honorary secretary, said that during the year which ended on March 31st, 1902, 70 nurses were sent into training and placed on the cottage nurses' register. Of these 35 were trained at Bury House and others in different districts or in maternity or cottage hospitals for periods varying from four weeks to 12 months. In regard to the work carried on by the associations in cottage nursing they did not want to fall back on district nursing because they were convinced that it was often for the benefit of the patients to have the entire services of the nurses during the time the illness lasted and there were certainly instances in which neither patient nor medical man would be satisfied with the attendance of a nurse for an hour or an hour and a half a day.

Visual Œconomics, with Rules for Estimation of the Earning Ability after Injuries to the Eyes. By Professor H. MAGNUS, M.D. Breslau, and Professor H. V. WÜRDEMANN, M.D. Milwaukee, Wisconsin. Milwaukee: C. Porth. 1902. Pp. 144. With five Plates. Price $2·50 (10*s.*).

CONSIDERING the numerous cases of injuries to the eyes that occur in civil life, entailing more or less impairment of vision and consequent loss of earning powers, it is surprising that so few appear in the law courts. Probably the majority are settled by arbitration, but when they do become the subject of litigation it is soon perfectly clear that the medical experts, the judge, and the jury have no kind of standard to which they can refer or on which they can rely to form an estimate of the money value of the damage done. The sum awarded is determined by a consideration of the circumstances of the plaintiff, the wealth of the defendants, and the opinion of experts, which is not infrequently contradictory. Much injustice is thus often inflicted.

The authors of this work state that the loss of an eye has in America been valued at sums varying from $1000 to $7000 (from £250 to £1750). Many circumstances have to be taken into consideration before justice can be done and the authors endeavour to deal with the subject in a mathematical and actuarial spirit. Their method of proceeding is explained in the following sentence: "Normal physiologic vision consists of a series of different factors—the central acuity, the visual field, light and colour senses, the adaptive faculty, the muscular movements, and the cerebral processes—all acting together in creating the sense of sight. We may, therefore, regard the act of seeing as a sum whose numerals are formed by the different functions; if one numeral be taken from the sum which represents the complete act of seeing, then the balance will be left—i.e., vision will be damaged to the extent of the loss of one of these visual functions; but vision is yet in existence in a limited way." A relative value must be assigned to each of these factors and this value must be dependent on the avocation of the individual, the effect of the lesion on the earning power of the patient, the prospect of recovery, the capability of the normal or uninjured eye learning to work, and other considerations to which we need not here refer. These points are treated mathematically and formulæ are given which will prove fascinating to some of our readers. Examples are given of the application of the formulæ to young and old artisans, to an architect or draughtsman doing fine work, to a travelling salesman, and to an iron moulder.

The treatise is founded on the essay by Professor Magnus on the estimation of the pecuniary value of injuries to the eye, but is practically a new work, having been rewritten by Professor Magnus and Professor Würdemann. It will surely fall into the hands of barristers and woe be to the medical witness who is not able to hold his own and has not made himself master of the contents. We recommend it strongly to everyone who is likely to be called as a medical expert in accidents affecting the eyes.

Introduction to the Study of the Dependent, Defective, and Delinquent Classes and of their Social Treatment. By CHARLES RICHMOND HENDERSON, D.D., Professor of Sociology in the University of Chicago. First English edition enlarged and rewritten from first American edition. London: D. C. Heath and Co. 1902. Pp. 397 and viii. Price 7*s.* 6*d.*

THE author's work, we are told in a puff preliminary which is marked with three asterisks and which appears on page i., has been welcomed with acclamation in some parts of America. "The first American edition was received in the United States as an extremely important contribution to the study of some of the gravest problems which society has to consider and copies of the edition are very difficult to obtain." The work before us, we are told, "although nominally a reissue of the former one, is practically a new book, it having been almost entirely rewritten in the light of criticism and further experience in charity organisation work." It seems, therefore, that as this is, according to its author, practically a new book it need not be taken for granted—we are not compelled as a matter of obligation to believe without inquiry—that this book, like the rare first edition, is an important contribution to "systematic study of the nature, condition, and social relation of dependents, defectives, and delinquents."

We cannot imagine that the book will be of use to those of our countrymen who are interested in this study or that it will, as the author supposes, "promote an understanding of the reality under consideration" or lead to "the goal of knowledge." The book, however, contains a few literary gems which it may be worth while to preserve. The sentiments expressed are not unlike those which were formerly in use in this country to improve the mind of the student of penmanship whilst he was employed with a quill in imitating the calligraphy of his teacher. Here are examples: "The dry light of science is focussed in the lens of affection" (p. 1). "Observation is the prime source of real knowledge" (p. 3). "All human beings are dependent on parents in infancy and helplessness is natural to the babe." "Extremes are met" (p. 74). We refrain from quoting more, for the following paragraph, which is to be found in the chapter on "The Criminal before the Law," seems to breathe out threatenings and slaughter against over-quotation (which is pilfering): "The more refined and just estimate of the value of literary products has created copyright laws protecting authors from theft of their spiritual labors." We are not informed how an "estimate" came to create a law.

We fear we may have given an unduly favourable view of the book and it is necessary therefore to warn anyone who might wish to read it that we have given specimens only of the most striking passages. In former days such excerpts might have been printed under the title of "The Beauties of Dependents, Defectives, and Delinquents." The book is illustrated by a bad reproduction of a photograph, or a reproduction of a bad photograph, of a most inartistic medal issued by the American Numismatic and Archæological Society to commemorate "the Twenty-fifth National Conference of Charities and Correction."

Contributions to Practical Medicine. By Sir JAMES SAWYER. Third edition, revised and enlarged. Birmingham: Cornish Brothers. 1902. Pp. 209.

THE lectures which comprise these contributions to practical medicine have been revised, pruned, and supplemented for the purpose of a third edition which as regards both size and finish is a far more ambitious volume than the two which preceded it. The lectures contain a fund of useful knowledge which has been acquired during a long and useful career as a physician in active practice and they cannot fail to arouse the interest not only of those who are themselves in practice but also of those who have still to learn the art and science of medicine. The first two chapters discuss the causes and the cures of insomnia which, for the purpose of description, is classified as symptomatic and intrinsic or in a somewhat more amplified form as psychic, toxic, and senile. The appetite for sleep, to use the author's quaint expression, should only be encouraged by natural means and by resorting to a variety of devices for changing the current of conscious cerebration—devices which are described in detail and include among others the practical method of the late Mr. Gardner, which was maintained as a secret until revealed by Dr. Binns. Symptomatic insomnia, according to Sir James Sawyer, should be treated on the principle of "*causâ cessante, cessat et effectus*"—a principle, by the bye, which has no general application to the operations of living protoplasm and clearly no special application to a rhythmical process such as sleep. The habits and periodicities engendered in the human body persist long after the stimulus which has evoked them ceases to operate. But this is a mere detail; the advice and recommendations which Sir James Sawyer supplies for securing the blessings of sleep are full of resource and should be very helpful to many of those who are often at their wits' end to know to what expedient to turn to alleviate inveterate cases of insomnia.

Gastralgia, which is the subject of the next chapter, receives a very fine clinical description and the author advises his readers not to diagnose cancer or gastric ulcer from merely subjective symptoms and not to assume that a patient is dyspeptic because he has pains in his stomach. As regards the treatment Sir James Sawyer boldly states that gastralgia, which is a more common complaint than is generally supposed, can be "cured" by arsenious acid which he recommends to be given in pill-form and in doses of $\frac{1}{60}$th of a grain combined with two grains of extract of gentian.

The subject of the Accentuation of the Pulmonary Second Sound of the Heart has a chapter to itself and as a diagnostic sign of increased tension in the lesser circulation it is regarded by Sir James Sawyer as pathognomonic. The author has frequently referred before to the significance of this physical sign and we believe he was one of the first to indicate its importance in the diagnosis and prognosis of mitral disease.

The treatment of habitual constipation, of eczema, of pulmonary tuberculosis by chloride of calcium, and of hæmorrhoids by unguentum ranunculi ficariæ, forms the subject matter of some excellent chapters which contain many invaluable suggestions of an entirely practical character. Ether as a vehicle for drugs requiring administration by the skin is apparently a favourite subject with Sir James Sawyer and for the purpose of testing its value he has conducted a series of experiments and has drawn up a formula for the exhibition of various drugs by this means which he claims to be entirely satisfactory. We cannot, however, convince ourselves that this method has any therapeutic advantage over inunction of the same drugs with valsol or vasogen as the vehicle, and, further, there are several practical objections to the use of ethereal solutions which readily suggest themselves.

This little book, with its quaint expressions and old-world air, is well suited to a profitable and enjoyable hour's reading.

The Academic Gregories. By AGNES GRAINGER STEWART. Famous Scots Series. Edinburgh and London: Oliphant, Anderson, and Ferrier. 160 pp. Price 1s. 6d. net.

THE Academic Gregories well deserve a place amongst the Scottish worthies who have been the subjects of this biographical series, and this work has been carefully and lovingly done by one whose intimate knowledge of the history of Scotland and whose keen sense of the humour of its people have combined to make the book extremely entertaining—it is instructive without being dull. It is not too much to say that most of the talented Gregorie family are entirely unknown to the vast majority of English readers, and with the exception of him who gave a powder to the world it is doubtful whether any one of them is at all a familiar figure. Many of them are well worthy of acquaintance. They were a fighting race and came of the Macgregors (of whom was Rob Roy) and they assumed the name of Gregorie before the year 1603. The first of them to obtain distinction was the Rev. John Gregorie of Drumoak, who suffered for his faith—he was an Episcopalian—and for his loyalty to Charles I. On one occasion he was somewhat discourteously treated by the Mr. Cant whose name has lived after him. From a contemporary account of the proceedings it appears that "Mr. Johne Gregorie ... .. at the visitatioun of the Kirk of New Abirdene teichit most lernidlie upone the 4th vers of the 2nd chapdour to the Collosians and reprehendit the order of our Kirk. ...... Mr. Andrew Cant, sitting besyde the reidar, as his use was quicklie cloisit the reidaris buke, and laid down the glass befoir it wes run, thinking the minister sould the sooner mak an end." In this, however, he reckoned without his host, for "he beheld and preicht half ane hour longer nor the tyme." The punishment inflicted was certainly a severe one, but in the circumstances it was possibly deserved. Cant, however, was allowed to preach back, and "he raillit out in his sermon aganes the said Mr. Johne Gregorie's doctrein." A truce between the combatants was ultimately arranged by the "mediatioun of the toune's baileis at a coup of wyne" when "they twa war satled with small credet to Cantis bussines."

A strong fighting tendency was manifested by most of the Gregories. The combative impulse which caused the Rev. Johne to fight Cant in the days of the Stewarts led his descendant Professor James Gregory to attack a brother physician with a stick. This occurred within the precincts of the University of Edinburgh and the assailant was prosecuted for assault and mulcted in damages. Most of the members of the family had a very good conceit of themselves and seem to have been richly endowed with the critical faculty. Dr. James Gregory's advice to Burns for the emendation of his verses is not devoid of interest. He did not like the title "On seeing a wounded hare limp to me, which a fellow had just shot at." "Fellow" was wrong, "it is but a colloquial and a vulgar word." "Shot," he continues, "is improper too. On seeing a *person* (or a sportsman) wound a hare, it is needless *to add* with what weapon, but if you think otherwise you should say with a *fowling-piece.*" The Professor then promises Burns that if he will call on him he will show some more poems written by a Mrs Hunter. "Mangled" is a coarse word. As an emendation for *blood-stained*, he opines that "bleeding bosom is infinitely better." Hamlet's estimate of Polonius is not entirely inapplicable to Professor James Gregory, yet he was a physician of discernment; he advocated the advantages of "change of air" and did not prescribe phlebotomy in all cases. He succeeded Cullen in the chair of Medicine at Edinburgh, lectured in a cocked hat, and accumulated a considerable fortune.

John Gregory, the father of Burns's critic, was born in 1724 and was professor of Medicine in the University of Edinburgh from 1766 to 1773. He had an interesting career. After studying anatomy at Edinburgh under Monro he went to Leyden and became the pupil of Albinus. Here he met Charles Townsend and Wilkes whom he described as a man "who wanted to be a fine gentleman and man of taste, which," he said, "he never could be for God and Nature had been against him." On his return journey he met the charming lady who afterwards became Mrs. Garrick. He went for a time to King's College, Aberdeen, and whilst he was there married a beauty and an heiress—the Hon. Elizabeth Forbes. In 1752 they went to London. He was made a Fellow of the Royal Society and through Mrs. Montague he became acquainted with the members of the literary society of that time, Johnson, the Burneys, Sir Joshua Reynolds. In 1756 he returned to Aberdeen. It was then that the Aberdeen Philosophical Society was started. It was a club which met at a tavern, wine was to be found on a side table and the evenings are described as having been "merry." Sometimes an essay was read. In the case of

Gregory as a rule his "discourse" was "not readie." Then a philosophical discussion was held and frequently Hume's sceptical speculations were attacked. Reid, one of the party, wrote to Hume to tell him that his company (although they were all good Christians) "would be more acceptable than that of Athanasius." Dr. John Gregory was an advocate for keeping children warm and did not approve the cold morning bath which it may surprise many people to learn was *de rigueur* in every well-constituted Scottish nursery in his time. Mrs. Montagué visited the professor when she was getting old and she did not "find acceptance" as the Scots have it in Edinburgh society.

It is quite impossible to mention all the illustrious Gregories, but enough it may be hoped has been said to show that the book is well worth reading. It is more than the history of a family, for it gives incidentally pleasant and graphic sketches of the home-life of the Scottish people as seen from the brightest side by a sympathetic student.

LIBRARY TABLE.

Traité de la Chirurgie d'Urgence. (A Treatise on the Surgery of Emergencies.) By FÉLIX LEJARS, Professor Agrégé at the Faculty of Medicine of Paris, Surgeon to the Tenon Hospital, and Member of the Society of Surgery. Third edition, revised and enlarged, with 751 figures, of which 351 are drawn from nature by Dr. E. DALEINE and 172 are from original photographs. Paris: Masson et Cie. 1901. Pp. 1045. Price 25 francs.—We have noticed an earlier edition of this work and all the praise which we have given to that is equally applicable to the present issue. Extensive alterations have been made, many chapters have been rewritten, and others are entirely new. Among these may be mentioned those on hepatic, sub-diaphragmatic, and perinephritic abscesses, irreducible and strangulated prolapses of the rectum, diaphragmatic hernia, acute osteomyelitis, and burns. Such extensive alterations have necessitated 134 additional illustrations and 133 extra pages. The general idea of the work is to provide the surgeon with all that he needs to know when called upon suddenly to deal with an emergency. A little consideration will show everyone that emergencies will include not only traumatisms but also many other conditions. To treat successfully sudden calls on his skill the surgeon must accustom himself to be prepared for these emergencies before they arise and this volume should prove valuable as an aid for this purpose. The illustrations are very numerous—for instance, there are 12 figures to illustrate the method of marking on the skull the fissure of Rolando and four figures show the several stages of Kocher's method of reduction of a dislocated shoulder. Some illustrations are given which demonstrate how some manipulations should *not* be performed. In all there are 18 illustrations of the reduction of a dislocated humerus. We commend the volume to the attention of all surgeons who read French.

Photographic Atlas of the Diseases of the Skin. By GEORGE HENRY FOX, A.M., M.D., Clinical Professor of Diseases of the Skin, College of Physicians and Surgeons, New York, &c. Parts 13, 14, 15, 16. Philadelphia and London: J. B. Lippincott Co. 1901. Price 6s. each part.—These four parts complete this useful atlas, the previous parts of which we have already noticed. They fully maintain the high level of the earlier portions and the whole will form a most valuable atlas of cutaneous pathology. The photographic method has many excellencies; its fidelity to truth as to the shape and size of lesions should count for much. The misrepresentation of the colour of the morbid condition is but a minor defect and in these plates this is to a great extent overcome by the colouring which has been added. The text is chiefly concerned with therapeusis and is likely to be of value to those who have had little experience in the treatment of skin diseases.

A Manual of the Diseases of the Eye and Refraction, including Treatment and Surgery. By GEORGE M. GOULD, A.M., M.D., formerly Ophthalmologist to the Philadelphia Hospital, and WALTER L. PYLE, A.M., M.D., Assistant Surgeon to Wills Eye Hospital, Philadelphia. Second edition, revised and enlarged, with 109 illustrations, some of which are coloured. London: The *Optician and Photographic Trades Review.* 1900. Small 8vo. Pp. 295.—This little manual is divided into two nearly equal parts. The first deals with the mode of examination and with the refraction and functional anomalies of the eye; the second deals with the diseases of, and the ordinary operations upon, the eye. Dr. James Thorington, a well-known authority on the subject of the refraction of the eye, has written the chapter on Retinoscopy. The theory of the ophthalmoscope is briefly but well given. There is nothing in the account of the diseases of the eyes calling for special notice. The symptoms of the various affections are shortly described and the treatment is in accordance with that generally adopted. Of the illustrations the least satisfactory is that which forms the frontispiece, stated to be after Jaeger, but which might advantageously be replaced by a better executed chromo-lithograph of the fundus. Judging from the place of issue it seems to be intended as a manual to be studied by those who are about to present themselves as candidates for the examinations held by the Spectacle-makers Guild or Society.

JOURNALS AND MAGAZINES.

The Journal of Physiology. Edited by Sir MICHAEL FOSTER, K.C.B., F.R.S., and J. N. LANGLEY, Sc.D., F.R.S. Vol. XXVIII., No. 3. May 28th, 1902. London: C. J. Clay and Sons. Price 5s.—The contents of this number of the *Journal of Physiology* are: 1. Fatigue in Non-medullated Nerves, by T. Grigor Brodie, M.D. Lond., and W. D. Halliburton, M.D.Lond., F.R.S. These experimenters, having observed that the assertion that the nerve fibres are insusceptible of fatigue rests on the excitation for long periods of time of medullated fibres, determined to repeat with some modification the experiments on non-medullated fibres. They selected the nerves distributed to the spleen and found that even after many hours of stimulation no evidence of fatigue could be demonstrated; nevertheless, they obtained proof that certain non-medullated as well as medullated fibres are injuriously affected by prolonged faradic stimulation, so that the spot which has been excited is no longer excitable until a considerable period of rest has elapsed. 2. A Note on Fœtal Muscle-spindles, by Laura Forster, M.D. Berne. A description is given of the appearances presented by muscle in fœtuses of the age of four, five, and six months. Dr. Forster shows that in the youngest embryo of these three the sheath of the muscle-spindles is very thin, that no lymph spaces are to be seen, and that the size of the fibres is more uniform than in the older embryos. 3. On the Formation of Lymph by the Liver, by F. A. Bainbridge, M.B. Cantab. Amongst other results it appears from Dr. Bainbridge's experiments that the intravenous injection of moderate quantities of sodium taurocholate or of pure hæmoglobin leads to an increased flow of lymph from the liver and to increased metabolic activity of the liver cells. 4. On the Local Reactions of the Arterial Wall to Changes of Internal Pressure, by W. M. Bayliss, with 11 figures in the text. Mr. Bayliss demonstrates that the muscular coat of the arteries reacts like smooth muscle elsewhere to a stretching force by contraction and to a diminution of tension by relaxation. These reactions are of myogenic nature and are independent of the nervous system and can be observed not only in the living state but in excised arteries some hours after death. 5. A Method of Estimating the Oxygen and Carbonic Acid in Small Quantities of Blood, by Joseph Barcroft, B Sc., and J S. Haldane, M D Edin , F R.S., with three figures in the text. The apparatus consists of a small glass vessel attached by tubing to a pressure gauge of narrow bore. The oxygen in the blood can be liberated by potassium ferricyanide and the resulting increase of pressure measured by means of the gauge and from this the volume of oxygen can be calculated. By similar manipulation, with the use of tartaric acid in the place of the potassium ferricyanide, the carbonic acid is subsequently determined. 6. Intestinal Absorption of Solutions by E. Waymouth Reid, M.B. Cantab., professor of Physiology in University College, Dundee, St. Andrews University The experiments of Professor Reid show that a physical explanation of absorption is not admissible. 7 The Proceedings of the Physiological Society

ERRATUM.—The price was wrongly stated in our review of Gaylord and Aschoff's "Pathological Histology" Our reviewer gave the price as 5*s* 6*d* , whereas it should have been 31*s* 6*d* net

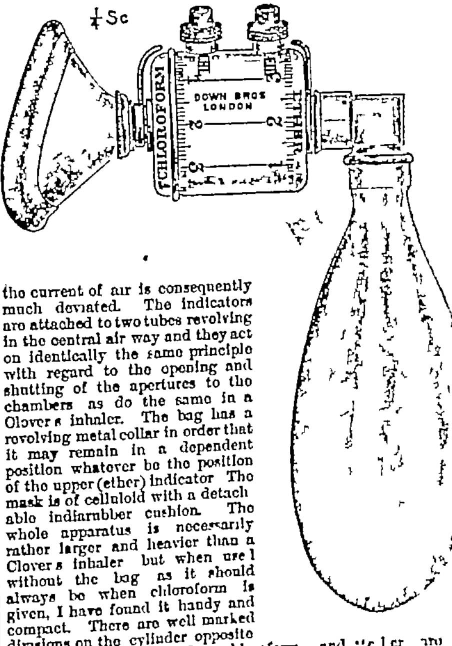
New Inventions.

PORTABLE SPRAYING APPARATUS FOR DISINFECTION

A CORRESPONDENT in whose judgment we have confidence has written to us in reference to the letter of "M O H." whose inquiry as to the best form of portable spraying disinfecting apparatus appeared in THE LANCET of May 31st p. 1562. Our correspondent says that he has tried every variety of such apparatus that has come to his knowledge, but that he has found most of them to be mere toys. He makes an exception in favour of a spray recommended by Dr W Leslie Mackenzie of Edinburgh, a medical inspector of the Local Government Board for Scotland. This spray, he says, answers admirably but is rather heavy and clumsy to use. It is made by Messrs. Benton and Stone, brassfounders, Bracebridge street, Birmingham We have quite recently learned, however, that the Thresh Disinfector Company has succeeded in diminishing the weight of Dr Mackenzie's apparatus by nearly 50 per cent. and has so modified it that it can be carried on a bicycle. The apparatus consists of a short force pump with air chamber attached to a foot piece. A rubber section tube dips into a collapsible canvas bucket holding enough solution to spray an ordinary sized room. The spraying nozzle is attached to a suitable handle and connected to the pump by about six feet of especially strong rubber tubing Upon working the pump a very effective spray is produced with which the ceiling walls, floors, and furniture of a room can be speedily covered with disinfecting solution. Additional lengths of brass rod are provided and a cross piece carrying two nozzles, so that large and lofty apartments or tents can be easily disinfected. When not in use the whole apparatus folds up and packs in the flexible bucket, occupying a space of 18 inches by six inches. The pressure obtained by the pump is from 40 to 60 pounds to the square inch and the spray produced is so fine that in the sunshine beautiful rainbows are visible in it The apparatus therefore is not a toy like many of the portable sprays and can be thoroughly relied upon Its cost is two guineas For many purposes of disinfection where spraying is not available Dr Thresh's portable "emergency" disinfector is very useful and satisfactory It consists of an oblong chamber five and a half feet high and two and a quarter feet square which is found to be sufficiently large to take an ordinary sized bed when properly folded. The apparatus is heated by an oil furnace specially devised for the purpose, weighs under two hundredweight, and can be moved on a hand-cart. Both the spraying apparatus and the disinfector are made by the Thresh Disinfector Company, Limited, 16, Great George-street, Westminster

AN INHALER FOR GIVING MIXTURES OF ETHER AND CHLOROFORM.

THE apparatus here described has been devised by me to meet a want which I have personally felt in the administration of anæsthetics and which I believe may have been shared by others who believe in the advantages of mixtures The object I have had in view has been to give ether or chloroform singly or together, in any proportion, during an administration and to be able to vary that proportion at will at an instant's notice. With these considerations I have had constructed an inhaler on the "Clover" type. Two Clover inhalers are in fact superimposed with an air way right through and an indicator at each end There are two chambers in the main cylinder The upper is the larger and will hold two fluid ounces (of ether). The lower smaller chamber will hold one and a half fluid ounces (of chloroform) The larger ether chamber is placed above on account of the denser vapour of this substance Separate hollow glass-ended plugs are fitted to each chamber A particular point in the apparatus is the central air way which is double the calibre of that of the ordinary Clover inhaler and allows ample passage for the strongest respiratory blasts, even when both indicators are turned well on and the current of air is consequently much deviated. The indicators are attached to two tubes revolving in the central air way and they act on identically the same principle with regard to the opening and shutting of the apertures to the chambers as do the same in a Clover's inhaler. The bag has a revolving metal collar in order that it may remain in a dependent position whatever be the position of the upper (ether) indicator The mask is of celluloid with a detachable indiarubber cushion. The whole apparatus is necessarily rather larger and heavier than a Clover's inhaler but when used without the bag as it should always be when chloroform is given, I have found it handy and compact. There are well marked divisions on the cylinder opposite the pointers and the words "chloroform" and "ether" are plainly marked on their respective chambers so that there may be no mistake as to which anæsthetic is being given. The instrument has now been used a considerable number of times and personally I have found it particularly useful in abdominal cases and in those cases in which mixtures of ether and chloroform are especially suitable



The method of administration that I employ in most cases is as follows First the bag is entirely removed and chloroform given for the initial respirations by slowly turning on the lower indicator until Mark 1 is reached and the patient is beginning to lose consciousness I then continue with ether by the upper indicator until Mark 2 is reached In this way a quiet anæsthesia is induced without the [illegible] tions produced by ether The administration can then be continued in the same proportion or in any proportion the anæsthetist desires, or chloroform can be shut off entirely and ether given alone with the bag on or chloroform given alone without the bag. Ether, it will be found, evaporates four or five times as fast as chloroform with the proportion E_2C_1 being used as measured by the indicators. The following are some results showing this:—

Sex.	Age	Part operated on.	Time under anæsthetic (minutes).	Proportions by indicator.	Quantities actually used.	
					Ether (drachms).	Chloroform (drachms).
F.	44	Breast.	55	E. 2; C. 1.	28	6
F.	46	Umbilical hernia.	47	E. 2; C. 1.	28	4
F.	30	Gall-bladder (bronchitic patient).	60	E. 1, C. 2½.	20	11

I have found that the initial stages of anæsthesia are somewhat prolonged, seven or eight minutes being the usual time to get patients well under, this being due to a tendency to somnolence. Struggling is, however, much reduced. The colour remains very good, the cyanosis of ether being rendered impossible by the free air passage, while the mixture of the two anæsthetics counteracts the pallor produced by chloroform alone. Other advantages are those attendant on the administration of mixtures. I have not yet given chloroform alone by this apparatus but consider it would be safe to do so if no bag were used, the free air-way giving plenty of oxygen. It may be remarked that the respective vaporisations of ether and chloroform vary so at different temperatures that the indicators are of little value whereby to judge the proportions actually being given. The temperature of operating rooms and theatres is, however, nearly always between 65° and 70° F. A little practice will quickly demonstrate the rapidity of evaporation when refilling has to be done and the water-chamber fitted to the ether compartment will help to regulate the vaporisation of the ether.

The instrument has been made for me by Messrs. Down Bros. who have executed the work exceedingly well.

Birmingham.

LITHOTOMY STRAPS.

THESE straps are made of stout webbing and are in three parts. The knee-straps are fixed round the flexed knees, the end of each strap, on which is a buckle, taking its attachment from the outer side of the knee. The long straight strap which in Clover's and similar crutches or straps passes round the patient under one shoulder and over the other is in these straps made extra long to allow of its being passed round the head of the table instead of round the patient. By this means, the table being considerably wider than the patient's body, which is really comparatively narrow, the knees, on the long strap being buckled to the knee-straps and tightened, are drawn backwards and strongly outwards, the separation approximating in extent to the width of the table. The advantages of these straps are: (1) the wide separation of the flexed legs and thighs; and (2) the portability and lightness. They are packed in a soft case weighing less than nine ounces and measuring eight by two and a half by two and a half inches and are made by Messrs. Mayer and Meltzer of 71, Great Portland-street, London, W.

Looking Back.

FROM

THE LANCET, *SATURDAY, JUNE 19*, 1824.

Foreign Department.

ROYAL ACADEMY OF MEDICINE AT PARIS.

(Sitting of the 23d. of March.)

M. ITARD read a paper on the spontaneous development of the prussic acid in the alvine evacuations He quoted two cases of this kind. The subject of the first case had an inflammation of the intestines, the other presented symptoms of inflammation of the liver. In both the individuals, the stools smelt strongly of bitter almonds. M. ITARD regards these facts as important in a medico-legal point of view, and concludes from them, that the existence merely of the smell of prussic acid in the fæces should not lead one believe that the person had been poisoned with this medicine. M. DELENS related on this occasion several facts, which shewed that prussic acid had been found in the perspiration, urine, and expectoration, accounting for the blue colour of these liquids.

Mr. DUPUY observed, that cows fed in certain pastures gave blue milk. M. VIREY quoted a case where cows fed with the *prunus padus*, exhaled a very strong smell of bitter almonds. The existence of prussic acid in the excrements of these animals was ascertained by the existence of the sulphate of iron. M. MARC related, that in Germany some persons had been poisoned by eating sausages, in all of whom a great quantity of prussic acid was spontaneously developed.—*Archives Generales.*

A NEW MODE OF OPERATING FOR STONE ADOPTED BY M. DUPUYTREN.

M. DUPUYTREN has just performed the operation for stone in a new mode, and with the aid of a new instrument. The operation may be called the transverse operation (*taille transversello*), and the instrument, the double *lithotome caché*, which consists of two blades, arranged so as to cut at the same time, both right and left in withdrawing the instrument from the bladder. The catheter is introduced, and the membranous portion of the urethra cut to allow the introduction of the *lithotome* into the bladder. On withdrawing the instrument it is opened, by which means it divides the prostate on each side into halves the one anterior, and the other posterior. By this method, the vasa deferentia, rectum, transverse arteries of the perineum, and the pudic is avoided in the operation. M. DUPUYTREN operated a few days ago on a child; since which no bad symptoms whatever has appeared.—*Archives Generales, May.*

J. K. STARLEY MEMORIAL FUND.—A fund has been started with the object of commemorating the work of the late Mr. J. K. Starley who in 1885 introduced to public notice the safety type of the bicycle. The form and extent of the memorial will necessarily depend upon the total sum received, but it is the intention of the committee of the fund to associate it with the pastime of cycling and to make it of general value to the great community of cyclists. Subscriptions and offers of assistance should be sent to Mr. J. C. Parkinson, honorary treasurer, or Mr. R. T. Lang, secretary, at 27, Chancery-lane, W.C. Cheques and postal orders should be made payable to the "J. K. Starley Memorial Fund" and crossed "London and Westminster Bank (Temple Bar Branch)."

THE LANCET.

LONDON: SATURDAY, JUNE 21, 1902.

The Election of Members of Council of the Royal College of Surgeons of England.

ON Thursday, July 3rd, the Fellows of the Royal College of Surgeons of England will proceed to the election of four members of the Council. These four members will form a sixth part of the whole of that body and therefore will have no small effect on the results of its deliberations. It behoves, therefore, all Fellows earnestly to take into consideration their duties with regard to this election. From their position as Fellows they have the right of voting for four of the candidates for these vacancies and their duty to the College requires that they should exercise this right with care. There can be no excuse for failing to vote, for under the present rules a voting paper is sent unasked to every Fellow in the United Kingdom of Great Britain and Ireland and the voting can be done without trouble or effort. Formerly, indeed, it was not so, and every Fellow who wished to vote had to journey to Lincoln's Inn-fields and personally to record his vote. This was by no means easy even for Fellows living in London and for the vast majority of Fellows living in the country it was practically an utter impossibility. So much, then, having been done to facilitate the voting of the Fellows it is their duty to avail themselves of their privilege and to vote. The numbers voting have indeed increased since these alterations were made, but even now only about half of the Fellows care to exercise the power of voting which they possess. This harmful apathy is mainly responsible for all the evils from which the Royal College of Surgeons of England suffers. Under the present constitution the Fellows of the College can only influence the action of the Council, the *de facto* governing body of the College, by care in the election of members of the Council. The entire *personnel* of the Council can be changed in eight years, for every year one eighth of its members retire by rotation. The reforms needed by the College could, therefore, be effected within a very short time were all the Fellows actuated by a sincere desire to advance the best interests of the College by the recognition of the claims of the Members and by electing to the Council only those Fellows who sympathise with the desire of the Members to have a share in the government of the College of which they form so important and so essential a part.

In the selection of candidates for whom to vote many Fellows experience great difficulty. It is not customary for the candidates for the vacancies on the Council to give any public expression of their opinions to the constituency and there is much to be said in favour of this practice; but the electors are left without any guide as to the views held by the candidates on the vexed questions of College politics. Frequently, therefore, the elector has to rely on the general surgical eminence of the candidate as a guide to his suitability to direct the affairs of the College. The general principles on which the posts on the Council should be distributed may be laid down as follows. There are 24 seats on the Council and of these four or five seats may be reasonably considered as belonging to provincial Fellows, and this is about the number of provincial Fellows usually on the Council. The 19 or 20 remaining seats must be divided amongst the 12 London medical schools. If possible every school should be represented and the number of representatives from each school should bear some relation to the relative importance of the school. On the present occasion for the four vacancies which exist there are eight candidates. Of the three members who retire by rotation one only, Mr. HOWARD MARSH, seeks re-election. It is a good rule that if a member of Council has served his term with credit to himself and benefit to the College he should be re-elected. Mr. HOWARD MARSH was first elected to the Council in 1892, but as he was then a "substitute" member his term of office came to an end in 1894, when he was re-elected for the full term of eight years. Mr MARSH has done good work on the Council and we consider it highly desirable that he should be re-elected. The other candidates are, in order of seniority, Mr. JOHN HAMMOND MORGAN of Charing Cross Hospital, Mr. HENRY HUGH CLUTTON of St Thomas's Hospital, Sir WILLIAM HENRY BENNETT of St. George's Hospital, Mr. CLINTON THOMAS DENT, also of St. George's Hospital, Mr CHARLES WILLIAM MANSELL MOULLIN of the London Hospital, Mr. GEORGE JORDAN LLOYD of Birmingham, and Mr JOHN BLAND-SUTTON of the Middlesex Hospital.

To consider these in order. Mr MORGAN is connected with Charing Cross Hospital, one of the most progressive of the smaller medical schools of London and at present without a representative on the Council. Of Mr. MORGAN's fitness for the post no more need be said than this—all who know him must recognise his suitability for the membership of the Council. Moreover, we consider that Charing Cross Hospital deserves a representative. Mr. CLUTTON is the senior surgeon of St. Thomas's Hospital. He is a good administrator and possessed of great energy and he would undoubtedly prove a most valuable acquisition to the Council. Moreover, by the death of Sir WILLIAM MAC CORMAC St. Thomas's Hospital has been deprived of its only representative and it would be surely very anomalous that so large and so important a medical school should have no representative on the Council. St. George's Hospital provides two sound candidates—Sir W. H. BENNETT and Mr. CLINTON DENT. This medical school is at present represented by Mr PICKERING PICK and may not unreasonably expect to have a second representative on the Council. Mr. MANSELL MOULLIN is surgeon to the London Hospital and the author of several well-known works on surgical subjects. The London Hospital at present has one member on the Council, Sir FREDERICK TREVES. Mr JORDAN LLOYD is the only provincial Fellow who is coming forward and since one of the vacancies results from the retirement of Mr. J. HARDIE, a provincial Fellow, it would only be reasonable that Mr.

JORDAN LLOYD should be elected. He will without doubt receive much support from provincial Fellows and we shall not be surprised if he is returned. Mr. BLAND-SUTTON is the last candidate whom we have to consider. He is attached to the Middlesex Hospital, which has already two such able representatives as Mr. HENRY MORRIS and Mr. PEARCE GOULD, and we cannot think it desirable that a third representative should be added.

Our consideration of the claims of all the candidates leads us to the conclusion that the most suitable choice the electors could make would be Mr. HOWARD MARSH, Mr. MORGAN, Mr. CLUTTON, and Mr. JORDAN LLOYD.

◆

Insanity and the Death Penalty.

THE trial of a man named SIMMONS, who was indicted for murder at the recent assizes at Dorchester, affords an example of the change which has taken place during the past 50 or 60 years in the attitude of the criminal law towards those mentally affected. The prisoner had committed his crime in the light of day, going into a public-house close to the club at which he was employed as steward and shooting his victim, a barmaid, with a revolver in the presence of several witnesses. There was evidence that he had given her presents, but if he had made other amatory advances to her there was nothing to show that he had been successful. Two days before the commission of the crime he had made accusations of intemperance and dishonesty against her to her employer which, if believed, would have insured her dismissal. Her employer, however, had refused to listen to his story. He had then purchased a revolver and two knives. With the revolver he shot her fatally and tried immediately afterwards to kill himself. Before shooting his victim he withdrew what was for him a considerable sum of money from the bank and in the bar he made some observation or proposal to her which was inaudible. Her reply, however, was given in evidence and was to the effect that she would have nothing more to say to him and the death-shot followed immediately.

It will be seen from the above brief account that the crime was on the face of it more or less deliberate; it was committed by an angry man upon a woman who had refused apparently to respond to his passion. Those concerned for the defence, however, were able to trace with considerable minuteness the history of the prisoner's childhood, youth, and early manhood. This history, with the narrative of the crime itself, had been laid before Dr. L. A. WEATHERLY of Bailbrook House, Bath, and Dr. W. B. MORTON of Brislington House Asylum, Bristol, with the result that these two gentlemen gave evidence in the witness box to the effect that at the time when the prisoner committed the crime he had not a full appreciation of the nature and quality of his act. Both expert witnesses agreed that he was at the time of the crime, and had been for long, suffering from the effects of "minor epilepsy." In the end, after a very brief consultation together, the jury found that the murder was committed by the prisoner but that he was insane, and Mr. Justice BUCKNILL, after expressing his concurrence with this finding, ordered him to be detained until His Majesty's pleasure should be known. Such a result to a trial based upon such facts would hardly have been possible in the days of the fathers of the present generation. In 1843, when DANIEL MCNAUGHTON murdered Mr. DRUMMOND, apparently mistaking him for Sir ROBERT PEEL whose secretary he was, evidence was given by medical witnesses and others on behalf of the prisoner which clearly showed that he was insane in the broadest and most popular sense of the term, suffering as he was from delusions which prompted him to fire the fatal shot under a sense of injury and to redress imaginary wrongs. Upon this evidence, and in the absence of any rebutting evidence, Chief Justice TINDAL stopped the case and directed the jury to find a verdict to the effect that when the prisoner did the act, which he had undoubtedly committed, he was not of sound mind. After this the House of Lords met to consider the question of how far insanity was to be held to exonerate a criminal from the consequences of his act and took the advice of the judges thereon. It was then laid down by the judges of the day, in answer to questions placed before them, that to establish a defence on the ground of insanity it must be clearly proved that at the time of the committing of the act the party accused was labouring under such a defect of reason from disease of the mind as not to know the nature and quality of the act he was doing, or that, if he did know it, he did not know that he was doing what was wrong. It was further declared upon this occasion that an accused person proved to be suffering from a delusion supplying a motive for his crime must be considered in the same situation as to responsibility as if the facts with respect to which the delusion existed were *real*. That is to say, that a man might be held irresponsible who killed another under the delusion that he was defending his own life from a murderous assailant, but must not be so excused if he took life merely because he was under the delusion that his victim had done some great injury to his character. In the case of the murder referred to above the law, as it was laid down in MCNAUGHTON'S case, if strictly applied, would hardly have excused the prisoner, of whom Dr. WEATHERLY expressed the opinion that when he did the act "he was overwhelmed with morbid delusive fears," and as to whose mental condition Dr. MORTON'S view was that "at the time he committed the crime he had not a full appreciation of the nature and quality of the act."

As far as we are aware, no decision enunciated by any court to which appeal has been made has varied the law as laid down for the guidance of judges in MCNAUGHTON'S case, but the development of medical and psychological knowledge and the tendency towards mercy natural to advancing civilisation and a milder age have modified the summing up of judges and the verdicts of jurymen. The result of this is that where it appears that a murderer acted under a delusion or under an impulse which a reasonable man would have controlled, whereas in his case there was an absence of self-control owing to mental infirmity, he may now escape the capital penalty which would formerly have been meted out to him. Of such conditions as these the case we have commented on appears to be a noteworthy example, but if there is trustworthy evidence of unsoundness of mind upon which a jury may act it is clearly only merciful and just that the person so afflicted should not be executed as a criminal.

itself could obtain access to the tank. The water from this tank was used for washing the milk-cans.

An outbreak at Balsall and Moseley Heath, near Birmingham, was investigated in 1873 by Dr. Ballard who thus sums up its etiology:—"1. Two wells upon adjoining premises occupied by milk-sellers became infected early in November with the infectious matter or virus of enteric fever through the soakage from a privy into them of excremental matters containing that matter of infection. 2. Through the medium of water drawn from these wells the milk supplied by these milk-sellers became infected and many of their regular customers who drank the milk suffered from the disease. The same infected milk having been sold to two other milk purveyors, some of the persons using the milk supplied by these milkmen also suffered in a similar manner. 3. There is no evidence that the disease spread in these districts in any other way than through the consumption of these infected milks" (Report of the medical officers of the Privy Council and the Local Government Board, New Series, 1874).

A serious outbreak of typhoid fever in Marylebone was investigated in 1873 by Mr J. Netten Radcliffe and Mr. W. H. Power, the former making the country inspections and the latter the inquiries in London. Mr Radcliffe was also accompanied in his inspections by Dr Whitmore, the medical officer of health of Marylebone, Colonel W Hope, V.C., and Mr. Chalmers Morton, representing the company supplying the milk, and myself as medical officer of health of St. George's, Hanover-square, and also sanitary adviser to the company. "Early in the outbreak Dr Murchison, whose family suffered very severely from it, satisfied himself that the only probable mode of introduction of the disease into his house was by the milk-supply. The suspicion having been aroused, he quickly ascertained that almost the whole of the families which were then affected with enteric fever within his knowledge and that of his professional friends, obtained their milk from the same dairy which supplied his household The preliminary inquiry had made it certain that the milk of six out of the seven farms supplying the dairy was, at the time of the outbreak, free from any suspicion of infection with enteric fever material. But with regard to the milk from the seventh farm the result was very different. Here a condition of things was found which rendered it highly probable that milk from this farm had been charged with enteric fever material and not improbably with the excremental discharges of a patient suffering from enteric fever, shortly before and during the earlier period of the outbreak in Marylebone *From this farm was obtained all the milk specially supplied by the implicated dairy for nursery use, the consumption of which milk, as has already been shown, furnishes the strongest evidence of the infection of the milk.* On June 8th the occupier of the farm died suddenly in the fourth week of an attack of ambulant enteric fever (typhus ambulatorius). For some time previous to the seizure it had been suspected that he suffered from some disease of the heart. The suddenness of the death at a time when it was believed by his medical attendant that recovery from the enteric fever had commenced led to the death being ascribed to the presumed heart disease and to its having been certified as occasioned by this cause, no mention being made in the certificate of the disease from which he was considered to be recovering at the time of death. The history of this case, indeed, is that of well-marked ambulant enteric fever. Previously to the hæmorrhage there had been no disturbed action of the bowels. After the hæmorrhage Mr. Humphreys gave directions that all discharges from the bowels and bladder should be kept out of the common privy of the farmhouse and buried somewhere outside the premises This direction was carefully carried out, and from the first hæmorrhagic stool to the last chamber slops all the discharges were removed to an ash-heap beyond the precincts of the farm buildings (as will presently be more fully described) and there the evacuations from the bowels were buried and the slops cast. No disinfectant was mixed with either the one or the other before being got rid of, for, on the one hand, it did not seem to be necessary from the place of burial or casting away, and, on the other, it was not advisable to retain upon the premises the great bulk of the evacuations passed within a brief period until a disinfectant had been procured. On August 12th, a son of the above patient, aged 13 years, was seized with enteric fever, and he passed through a slight but well-marked attack.

"A series of carefully executed excavations were carried out under the supervision of Colonel Hope, V C, one of ourselves and the manager of the implicated dai also present, to determine whether soakage from t and from the drains of the farmhouse could find into the dairy well. A previous examination of the of the well, the water having been pumped out purpose as low as practicable, disclosed a of soakage through the interstices of the brick on the south side of the well, three feet six inches the inlet of the drain from the feeding well and feet from the surface. Other more doubtful point soakage existed, which need not be described. excavations proved conclusively (1) that no soakage possible from the privy into the dairy well; (2) that soakage had taken place either from the surface y drain or from the dairy drain into the well; and (3) th no soakage from the farmyard drain or the farmyard elsewhere had passed along the upper part of the in which the conduit from the well in the meadow to th dairy well was laid. These questions having been carefully put aside a trench was run up to the yard wall from the garden plot on the south side, a little to the east of the position of the well, and on digging beneath the of this wall unquestionable signs of soakage of some foul matter were found. On this being discovered an excavation was made between the well and the yard wall and a line of soakage disclosed along the foundation of the wall through the made earth intervening between the wall and the well to the point where soakage had been discovered in the well. The reason of the growing foulness of the from this well, which had caused its disuse some time before for drinking and cooking, now became at obvious. The soakage could only come from one direction —that of the pigsty. The yard wall and the southern wall of the pigsty were continuous. The drainage of pigsty flowed to the south side of the wall and accumulated. The surface drainage from the yard also occasionally dammed up against the wall, as one us at the time of the first inspection of the premises occasion to see. Now there can be no reasonable doub from the result of the excavations, that the drainage of th pigsties and of the yard had in the progress of time mad its way along the foundation of the wall, a distance of about 25 feet, to the vicinity of the well and then soaked through the intervening soil into the well. The latter process from the nature of the soil would be a slow one, but it had been accomplished so effectually that the clay which constituted the bulk of the made ground between the wall and the well was, along the line of soakage, reduced to the consistence of very soft paste. Against the wall along the foundation of which this soakage takes place and close to the pool formed by the drainage from the pigsty is the ash-heap of the farm. In this ash-heap were buried all the evacuations from the bowels of the sick occupier of the farm on June 1st, 2nd, and 3rd, and upon it were cast all the chamber slops of the sick man's room from June 1st to 8th. *In other words, by an unhappy and altogether unforeseen chance and in carrying out precautions to obviate any possibility of mischief the matters from which mischief was most apt to arise were deposited in perhaps the only spot on the farm premises where they would certainly find their way into the water used for dairy purposes*

"For the ultimate purpose of this inquiry it is sufficient to have shown a probability, amounting for practical purposes to a certainty, that (1) the outbreak of enteric fever which forms the subject of inquiry was caused by milk infected with enteric fever material, (2) that this milk came from a particular farm, and (3) that the water used for dairy purposes on this farm contained excremental matters from a patient suffering from enteric fever immediately before and at the time of the outbreak" (Report of the medical officer of the Privy Council and the Local Government Board, New Series, No II, 1874)

In the seventh annual report of the medical officer of the Local Government Board, 1877, is a report on an unusual prevalence of enteric fever at Ascot during a period of four years and a half by Dr E Ballard, from which I quote the following "In the middle of 1873, at the very time that the outbreak in Marylebone which was traced to the milk supply of a particular dairy was in progress, three cases of enteric fever occurred almost simultaneously on the top of the ridge of hill on which the village of Ascot stands. ....

"The three cases occurred in persons who had recently been in London, *and two of whom had certainly whe there used the milk of the particular dairy*

Coronation Rejoicings and Fire.

THE recent fire in Queen Victoria-street and the terrible loss of life which accompanied it have called attention, as attention has been called before, to our Metropolitan Fire Brigade system and particularly to the means for rapidly summoning the assistance of the fire brigade and to the appliances provided by the brigade for enabling persons to escape from burning buildings. We are now expecting in the near future the coronation of King EDWARD VII. and his beloved QUEEN and one of the modes of celebrating it is to consist in illuminations on a scale never before attempted in London, while at the same time enormous crowds will hinder the operations of the fire brigade should any necessity for them arise, and in many miles of thoroughfare temporary stands of a highly inflammable character will be a grave source of anxiety and danger should any fire take place in their neighbourhood. In these circumstances it will be the duty of everyone who seeks to exhibit loyalty by illuminating his house or windows to act with extreme care and with consideration for possible danger to his neighbours and to himself.

With regard to illuminations in which electric light is used there can be little fear of conflagration; there is no naked flame to come in contact with other decorations, and the probability of serious accident arising through short-circuiting is not great. In the case of gas jets there is often a naked flame which may come in contact with a flag or with unprotected woodwork, but care will prevent this and a fire so occasioned will be, as a rule, outside and not inside a substantially built house Illuminations, however, in which gas or electricity play a part are usually exhibited by the wealthier classes and are erected by skilled workmen It is in the display of what we may call "amateur" illuminations that danger of accidents will lie, and where accidents take place there will always be a possibility of serious results owing to the fact that the inhabitants of many of the houses will be out in the streets and that the crowd and confusion will hinder the movements of those who otherwise might render assistance. These amateur decorations will consist chiefly of lights contained in coloured glass receptacles or Japanese lanterns, and once safely lighted and placed outside the house there is no great danger even in these. The dangers that may arise are likely to occur in lighting them; this should be done by a responsible person and if it is done inside the house caution should be exercised lest window curtains and other inflammable substances may come near them. In all cases where exposed lights are used attention should be paid to the possibility of window curtains coming in contact with them outside the house—that is to say, all windows behind illuminations are best closed. With Japanese lanterns, which are always liable to catch fire, and the glass receptacles referred to, if these are suspended, wire of serviceable stoutness should be used and never string Any makeshift devices, such as have been suggested at times on such occasions by foolish persons, consisting in placing candles or lamps close to windows inside the house, should be avoided even though they are prompted by the loyalty of persons too poor to afford more elaborate exhibitions.

There is one form of rejoicing akin to illumination which should be absolutely forbidden, and that is the letting off of fireworks of any kind, either in the streets or from houses. At the time of popular rejoicing over the relief of Ladysmith and of Mafeking in some parts of London rockets were let off from house-tops with absolute disregard as to where the rocket-sticks might fall, and we do not know that any police-court proceedings followed. Indeed, in one case of which we are aware inquiry at a police-station had as its result the reply that the police were powerless to interfere as long as fireworks were let off from private premises—that is to say, that a man might discharge a succession of rockets from his house-top over, or into, the crowd in the streets, the houses of his neighbours, their vehicles, and their horses, and the police could not do anything to stop him or to have him punished. If this attitude of the police is correct we can only congratulate London that popular rejoicing does not take the form of the discharge of firearms and that rockets are used and not "pom-poms." Fireworks of any kinds are dangerous in careless hands and near buildings. The smallest, such as squibs and crackers, let off in a street may injure eyesight or cause a temporary rush or panic in a crowd. A rocket does not always descend in the form of a stick; it sometimes fails to rise, but whether it comes down as a blazing firebrand or a smouldering lath it may go through a window and set fire to a house, it may frighten a horse, or it may hurt a human being. A rocket-stick, even if quite extinct, falling among the upturned faces of a crowd might do serious damage. Whatever means, however, are taken by the police to forbid imprudence or to supervise the safety of London during the nights succeeding the coronation the real safety of London will have to lie in the prudence and good sense of individuals, and it will be the duty of all who have influence with the careless and irresponsible to use it to the utmost. Any accident connected with fire commencing at such a time might have terrible results that on an ordinary night might not occur, while the illuminations that are to take place next week promise to be practically universal and the crowds prodigious

Annotations.

"Ne quid nimis"

THE PSYCHOLOGY OF JUBILATION.

"MY masters, are you mad, or what are you?" was the question asked by Malvolio and on several occasions during the last two years he might have put the same query As a nation, and perhaps even individually, we are more sober in adversity than in success, certainly we are much more dignified in the dogged acceptance of conditions that have gone against us than in the exuberant manifestations of an accomplished victory Why should the burning of gas, for example, the making of noise by gun-firing, bell-ringing and shouting, feather-tickling and squirting be the outward signs of joy? Partly because they are the local signs of a desire for the general diffusion of what is agreeable individually (does anyone, however, like to be squirted at?), partly because they are the means for an actual physical restoration of balance by the provision of an outlet for pent-up explosiveness. Of course, such exuberance is an insanity of the moment. When it is over we make excuses for having been so demonstrative, we look sheep-faced when brought to reflection on the temporary aberration, but we are able to settle down to prosaic existence much more quickly than would have been possible if we had fought against the volcanic explosion of feeling and had endeavoured to cool ourselves down by more gradual and rational methods. In these public outbursts of enthusiasm it is the night-time which sees the culmination of seismic social disturbance, because inhibition is then at its lowest ebb. The light of day has gone, we must have more light, so we flout the quiet heavens with artificial fire. The silence of night is oppressive, we must have a soothing noise. Shout, then; laugh and sing, until the larva of jubilation has run out and we can rest, lapped in the peace that follows an irresistible letting-go. So might argue, if arguing it can be called, the crowds filling our streets upon Mafeking nights and Peace nights, and the affinity of this frame of mind to madness must strike observant men. The essential difference between the madness of the man inside the asylum and the insanity of the man outside is that the former has his failure of inhibition at times when there is no excuse for it except his own personal morbid condition, when, therefore, the rest of society is unprepared and resents the forcible exhibition of what is against its feeling of the moment. The latter's outburst exactly represents that feeling and the sanity of what is really a manifestation of insanity is accepted by all. Are these ebullitions good for the community? We think that they are, though we feel that this is tantamount to confessing that the march of civilisation has not modified human nature so much as might be believed. The world is very much as it was long ago. There is still the same tendency to explosiveness, to mind-storms, to loss of inhibition, and it takes very little to seduce the sedate citizen into the destructiveness of the child, the "rag" of the university student, or the hooliganism of the man of the street. Habit may do much. Events of the last three years have been of the nature of a new experience; there was no preparation, no gradual adaptation to new conditions, while everything that argued for explosiveness was provided. But perhaps we are now more acclimatised. We have had time to prepare for the Coronation and we shall probably display less convulsive and hysterical jubilation than we should have done had the occasion been suddenly sprung upon us.

THE CIVIL SURGEONS AND THE LATE WAR.

THE civilians who took part in the South African campaign have returned, or are returning, to their usual avocations with a store of new experiences which cannot fail to be of value to them, whatever their calling in life. Some will have more opportunity than others of turning to account the practical lessons that they have learned, but all our volunteer and auxiliary forces are coming back to civilian life with their views broadened, their knowledge of men and matters immensely enlarged, and their qualities of endurance and self-reliance tried in the fire of experience. With regard to the civil surgeons now resuming their peaceful callings we wish to call attention to a suggestion made by Surgeon-General A. H. Keogh, C.B., the Deputy Director-General of the Army Medical Service, at the dinner of the South African civil surgeons last week. Surgeon-General Keogh thought that civil surgeons who have seen service in South Africa might well organise themselves into field hospital units in times of peace, and the idea is, in our opinion, a thoroughly valuable one. One of the most striking episodes in connexion with the war was the promptitude, nay eagerness, with which a large number of medical men voluntarily offered themselves for active service, in many cases giving up lucrative civilian positions, regardless of the fact that they might be sacrificing their lives as well as their professional prospects. Undoubtedly the Army Medical Service was at the time that the war broke out seriously undermanned. The country really stood in need of the help of civilian medical volunteers and this fact was, not too quickly or too gracefully, recognised by the War Office. At once all possible vacancies were filled. These volunteers have discharged their duties admirably and while doing so have got into touch with their military colleagues in a manner that certainly ought to be made available for future use. The union now made should be cemented. The civil surgeons have seen the work of the officers of the Royal Army Medical Corps in the field, they have taken part in their duties, and they now know the peculiar difficulties which the medical military officer has to encounter. For the future, whenever the civilian medical man can help his colleague of the Army Medical Service he may be trusted to do so. To return, however, to Surgeon-General Keogh's suggestion. Willing as the civil surgeon showed himself to help his brother in the army, the services which he rendered, valuable and effective as they were and rightly as they earned the praise of the authorities, would often have been enhanced by a knowledge of army routine and an appreciation of military discipline. Supplementary help to our armies in time of war must always be more effective if organised in time of peace and under the direction of, or at any rate in some degree in touch with, the military authorities. The suggestion made by Surgeon-General Keogh to the effect that civil surgeons who have seen service in South Africa should organise themselves into field hospital units rather than attach themselves to volunteer regiments is one that should be acted upon promptly, we consider, if the lessons of the war so far as they affect the civil surgeon are not to be largely lost. In the late campaign the field hospital proved itself to be a unit of the greatest importance. We have, however, no field hospitals maintained in time of peace and the question how such hospitals are to be organised is a matter for consideration. The first thing to be done is for the civil surgeons to signify their willingness to form themselves into such an auxiliary branch of the service and then to draw up a working scheme. We know that there are difficulties in the way of such a scheme, but they are not insurmountable, and as far as the matter of equipment is concerned we do not anticipate financial difficulties. That the Director-General of the Army Medical Service would welcome such a scheme there can be no doubt, and we trust that before long the field hospital in time of peace will have become an established institution.

FREE LIBRARIES FOR THE BLIND.

THERE is a feeling at once natural, general, and laudable which leads men and women at a time of national rejoicing to seek out and to help proper objects of charity. The feeling arises, no doubt, from that sympathy with his fellow-men which dwells to a greater or a less extent in every human breast. It is the same feeling, dependent upon the same sympathy, which makes a man laugh more readily when others can laugh with him and which draws tears to a woman's eye when she sees other women weep. At the present moment when thousands of happy men and women in England are preparing an extra happiness for themselves in the acclamation of a well-beloved Sovereign some such sympathy spreads far and wide. Every man who rejoices feels that he would do something to help those to whom joy comes less easily, if at all. In this way such times as these of coronation celebrations are a double blessing. The happy rejoice and the unhappy—the poor, the sick, the blind—have at least some alleviation shed upon their misery. With reference to the last-named class of sufferers—the blind—we wish to draw the attention of our readers to the Home Teaching Society for the Blind, a society whose benevolent efforts, successful though they are in adding pleasure to the scant enjoyment of hundreds of the poor blind, might be still more so but for the need of funds. A letter from the president of the society, Viscount Midleton, appears in the *Times* of June 16th and contains this sentence: "Want of money alone limits the extent of its work." As the letter points out, the Home Teaching Society has a centre for exchange as well as a complete organisation for free distribution of books. We cordially agree with the society's president in thinking that the philanthropic who wish to commemorate the Coronation in a special way in connexion with those who suffer from blindness will be better advised in aiding the established society than in seeking to found an additional free circulating library, and we can imagine no more suitable object for such specially directed charity than the Home Teaching Society for the Blind.

ANTECEDENTS AND TERMINATIONS OF EPILEPSY.

DR. WILLIAM SPRATLING, medical superintendent of the Craig Colony for Epileptics, New York, contributes an interesting article to the *Journal of the American Medical Association* of May 3rd on some points connected with the antecedents and terminations of epilepsy, information concerning which is not usually given in text-books. The article is based upon observations made during several years at the Craig Colony for Epileptics, an institution offering exceptional opportunities for the study of the disease in its various aspects. In the United States, says Dr. Spratling, one person in every 500 of the population suffers from epilepsy, a ratio which is about the same as that prevailing in England. From a study of 1100 cases during the past six years in regard to etiology it appeared that in 15 per cent. of males and 17 per cent. of females epilepsy existed in and was inherited from the parents (similar heredity). Among other important causes alcoholism was present among the parents in 16 per cent. of males and 12 per cent. of females, insanity in the immediate ancestors was met with in 7 per cent. of males and 10 per cent. of females, while parental tuberculosis was found in 15 per cent. of males and 12 per cent. of females. Taking the chief hereditary factors above mentioned it was found that they could be traced in 56 per cent. of the entire number of cases observed. Cerebral palsies sustained during childhood were recognised as the cause in 117 cases, or 11 per cent. of the total cases, while head-injury during birth or childhood accounted for a few more. The fevers and infections of childhood—measles, scarlet fever, diphtheria, and obscure forms of intestinal disease—probably assisted in the production of epilepsy in some cases but no exact conclusions could be reached regarding their etiological value. Epilepsy arising from hereditary sources almost invariably manifested itself during childhood, puberty, or early adolescence, but when appearing for the first time after adolescence it was probably due to syphilis, traumatism, or some form of toxæmia such as resulted from alcohol, absinthe, or lead poisoning. Epilepsy tended to shorten life, the greatest danger being the occurrence of the status epilepticus, a condition which was likely to develop in any form of epilepsy at any time and which was the cause of death in 25 per cent. of all deaths among epileptics. Epileptics were unusually prone to disease of the heart and lungs. Thus of the deaths in Craig Colony during six years 24 per cent. were due to pulmonary phthisis, 10 per cent. to organic disease of the heart, and 8 per cent. to pneumonia. Under proper treatment—i.e., under conditions which enabled the physician to control absolutely the habits of the patients—from 8 to 10 per cent. of epileptics, if taken in time and treated long enough, might be made to recover. The most discouraging symptom was mental enfeeblement or dementia which affected fully 90 per cent. of all cases of epilepsy when the disease had been in existence some years. Treatment comprised the giving of bromides and a simultaneous withdrawal of all sodium chloride from the patient's food (salt starvation). The sedative action of the bromides was thus enhanced—almost doubled. The addition of opium (Flechsig) or of adonis vernalis (Bechterew) facilitated recovery in some cases. Epileptics should be promptly treated in case of constipation with aperients, and beta-naphthol or salol in five-grain doses should be given with the aperient. Status epilepticus should be treated with a mixture of chloral, opium, and bromides. The diet of epileptics should be always plain and unseasoned—e.g., milk, eggs, rice and cereals, and fruit. Meat or fish should be taken sparingly at noon and the evening meal should always be light.

INDUSTRIAL DANGERS IN THE TRANSVAAL.

DR. THOMAS OLIVER, one of the physicians to the Royal Infirmary, Newcastle-upon-Tyne, sends us an interesting communication on this subject which we have had pleasure in reproducing in our columns.[1] Dr. Oliver speaks with authority on industrial dangers. He is the confidential adviser of the British Government on those matters and has recently published[2] the best English work of recent years on this important branch of State Medicine. It appears that many of our north-country colliers who had previously emigrated to South Africa in search of lucrative employment have during the last two years returned to their homes in Northumberland and Durham owing to the closing of the South African mines and the continuance of the war. These miners, we are told, present the appearance of men broken down in health who sooner or later succumb to pulmonary disease—they return to their homes in this country "only to die of phthisis." As Dr. Oliver has in the course of his out-patient practice become familiar with the form of disease presented by the Transvaal miners, he has been at considerable pains to write a very useful description of the symptoms and physical signs of the malady as it occurs among these workers and has suggested rational principles for its prevention. He has done this public service with a view, if possible, of inducing those in authority to bring about improved and more sanitary methods of mining in the Transvaal, as well as of advocating the necessity for revising the mining regulations of that recent addition to the British Empire with a view to the saving of life and the promotion of health among the miners. To those who are especially interested in this question no better text-book could be recommended than that which Dr. Oliver himself has provided in his recently-published Treatise on Dangerous Trades, which embodies several contributions by eminent authorities at the Home Office and elsewhere in England and Scotland. In particular we would refer to the chapter on the Regulation of Injurious or Dangerous Occupations in Some of the Chief European Countries, and also to the section on the Vital Statistics of Miners and Others Engaged in Dust-producing Occupations, which forms an important part of the earlier pages. It is, of course, true that in Great Britain there is no industry precisely analogous to the gold mining of the Transvaal and therefore that the experience of this country cannot supply complete instruction as to the best methods by which the health and life of gold miners may be safeguarded; nevertheless, Dr. Oliver tells us that gold mining is, *inter alia*, a dust-producing occupation—that "gold miners' disease" is essentially a slowly-developing pneumoconiosis due to the inhalation of dust; it is therefore a malady akin to stonemasons' or steel grinders' phthisis. In using the term "phthisis" to describe this particular malady we are pleased to note that Dr. Oliver is careful to distinguish miners' phthisis from the tuberculous infection to which, unfortunately, the same name is still indiscriminately applied, even here in England. In the miners' phthisis of gold workers there are few of the well-known signs of the tuberculous malady. Hæmoptysis, for example, although it sometimes occurs, cannot be said to be a symptom of the disease. There is no night-sweating; it is essentially an afebrile disease, and until towards the approach of death there is no rise of temperature, and even then it may not be very marked. In all these respects, and also in regard to the physical signs which accompany it, gold miners' phthisis contrasts strongly with pulmonary tuberculosis and shows a striking similarity to the fibroid lung disease or pneumoconiosis of this country. On the question of treatment Dr. Oliver has few suggestions to offer. If any good at all is to be got by treatment he thinks that this can only be attained by the gold miners renouncing their work in the very earliest stages of the illness and following outdoor employments. He is, however, of opinion that until a larger experience of the disease has been gained it would be better to send the patients for change of air, not to the seaside but inland to fairly high altitudes—say, 700 feet or more above sea level. It is therefore mainly to preventive science that we must look for a reduction of the evils which South African miners suffer as a consequence of their avocation, and Dr. Oliver's thoughtful essay will not have been written in vain if it awakens in the right quarter the conviction that something in the direction of prevention is practicable and therefore ought to be attempted forthwith.

DINNER OF THE OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

ON June 13th, following the delivery of the Bowman Lecture by Professor Fuchs of Vienna, the above society celebrated its majority by a dinner at the Trocadéro, Piccadilly, the members and guests numbering nearly 100. In the absence of the President, Dr. David Little, through illness, the chair was worthily filled by Dr. D. Argyll Robertson of Edinburgh. The Royal Toast having been honoured Dr. W. H Allchin, President of the Medical Society of London, proposed "The Welfare and Prosperity of the Ophthalmological Society." Specialism, he said, had come to stay, and ophthalmology more particularly justified itself owing to the time necessarily devoted to special study and technique. Before the establishment of that society ophthalmic subjects and cases were brought before the Medical Society of London and he cited some remarkable instances of the heroic treatment adopted in former days. He observed that during the past 10 years no communications on ophthalmic subjects had been received by it. Many Fellows of the Medical Society of London were original members of the Ophthalmological Society of the United Kingdom, the comprehensive title of which, as well as the eminence and number of its members, some of whom were present from India and the Colonies, testified to its extent and prosperity. Sir Anderson Critchett, who proposed in graceful terms "The Health of the Bowman Lecturer," said that it was as difficult to praise a friend before his face as it was to disparage an adversary behind his back. Professor Fuchs was known as the writer of the most popular work on ophthalmology in the whole world, as well as a most successful teacher and practitioner. He was worthily numbered among the pre-eminent men in medicine whom Vienna had produced. Professor Fuchs, in reply, referred to a statement that "hospitality was most developed in primitive countries and disappeared with the progress of civilisation." England, maintaining its primitive hospitality, welcomed men who were sometimes driven from their own countries on account of advocating new ideas, and maintained her tradition of freedom in science as in government. In his younger days he had studied in London and was greatly indebted to Bowman and Critchett for their teaching and work. He congratulated Sir Anderson Critchett on having so well maintained the honour of a celebrated name. Mr. H. R. Swanzy (Dublin), who proposed "The Health of the Guests" in a speech at once witty and in good taste, congratulated the society on maintaining good fellowship among its members, and welcomed the guests, among whom he mentioned Sir William Church, Bart., President of the Royal College of Physicians of London; Dr. Landolt of Paris; Dr. Allchin; and Mr. H. W. Page, President of the Neurological Society. Sir William Church and Dr. Landolt replied, and after a tribute to the chairman and secretaries a most enjoyable entertainment was brought to a close.

THE APPROPRIATE FORM OF LENS FOR CONICAL CORNEA.

M. J. JANSSEN read a paper on this subject on May 5th before the Académie des Sciences, an abstract of which appears in the *Comptes-Rendus* of May 20th. He proposes the use of a deep meniscus lens, the inner surface of which is concave to such an extent that it is approximately parallel to the convex surface of the conical cornea while the outer surface is convex to the extent of a normal cornea. Mention is made of only one case for which such lenses were made 10 years ago and succeeded in restoring sight almost to normal (*une vue très sensiblement normale*). It is obvious that the effective area of the meniscus must not measure more than half an inch from side to side, or the weight of these deep menisci would be intolerable. Further, such glasses would be exceedingly costly if the inner surface were made to correspond exactly with the conical cornea of each individual. Practically very deep concave plano-spherical lenses of known curvature might be kept in stock by opticians. On finding the biconcave trial lens which gives with a patient the best visual result it would be an easy matter to determine the requisite additional curvature that would have to be ground on the outer surface which would make the meniscus of the same strength as the trial lens. A lens made in this way should be more suitable for a conical cornea than the ordinary biconcave lens, while the cost of its manufacture would not be excessive.

AN OUTBREAK OF RABIES.

THE strong manner in which the Rabies Order was enforced and the Muzzling Order carried out in the face of so much bitter outcry and opposition on the part of the fanatical section of the dog-owning community has borne good fruit in England, but that it is still necessary not to relax any precautionary measure is shown by the fact that even within the past few days a case of rabies has been reported from Wales. The rabid animal was a Scotch collie belonging to a farmer in Pembrokeshire and it commenced its wanderings one Sunday evening. On the following Wednesday it was seen, and, unfortunately, ran amongst a lot of children who were coming out of school, biting one of them. Eventually it was shot, and a post-mortem examination, made by the county council veterinary inspector at Haverfordwest, revealed evidence of rabies, this being subsequently confirmed by inspectors sent from London by the Board of Agriculture. Unluckily, during the three days when the collie was away, its wanderings spread over a large area and it is impossible at present to trace the exact amount of damage done. Several dogs are known to have been bitten and these have been destroyed. A sheep, one of a flock through which the dog was seen to pass, has died from rabies, and the probability is that many animals were bitten and may become mad. The seriousness of the affair has caused considerable excitement and comment in the district, the Muzzling Order has again been enforced, and it is to be hoped that the precautions taken will attain the desired result. The western district of Wales is the only one in Great Britain in which rabies exists or has recently existed, and when once this part can be declared free it is to be hoped that this dreaded disease will become as complete a stranger to our shores as rinderpest and other diseases which have been stamped out by the Board of Agriculture and its veterinary and administrative advisers.

LORD SALISBURY AND THE LONDON WATER BILL.

ON June 12th the Prime Minister received a deputation who attended to request him to use his influence to support the London Water Bill and to urge the claims of the metropolitan boroughs to receive adequate representation on the Water Board. The deputation included the mayor of the City of Westminster and the mayors of the boroughs of Chelsea, of Camberwell, of Hackney, of Holborn, of Islington, of Lewisham, of St. Pancras, and of Stepney, and representatives from the urban districts of Beckenham, of Chiswick, of Kingston, of Isleworth, of Surbiton, of Twickenham, and of Wimbledon. The awakening interest in the water-supply shown by some of the metropolitan civic authorities is a wholesome sign, but it is becoming manifest somewhat late, and even now a small proportion only of the metropolitan mayors seem to have been present as members of the deputation. Lord Salisbury did not appear to feel much enthusiasm for the Water Bill, nor did he take a particularly cheerful view of its prospects A perfect scheme, he said, was unattainable and he agreed with the deputation that the "present form" of the Bill is the best that they could attain. The London County Council was convinced that it ought to have control over the water supply—that was nothing against the London County Council On the other hand, there was no reason why the deputation should not resist the Council in that matter In fact, the fate of the Bill would largely depend on the efforts of the deputation.

PHYSICIANS AND THE FRENCH PRESS

THE physicians of no nation in the world hold a higher standard of medical ethics than do those of France.[1] It is by no means so certain that the general public in France quite appreciate the high standard of medical etiquette which is observed by the leading members of the medical profession One of the most popular of the Paris papers lately[2] contained a short article entitled "Hygiène et Médecine" in which the name and address were given of a medical man who is said to be an attractive writer and a well-known specialist. Three of this gentleman's recently published books are then lauded. Of the first of these ("La Peau et l'Estomac") it is said that it enables the reader to put his finger on the causes of maladies connected with these organs, gives the newest hygienic precautions to be adopted for avoiding them, and the most rational methods for their treatment. All this useful information may be had for one franc. The second book ("Consultations pour les Arthritiques") deals not only with rheumatic and gouty affections but gives advice also concerning diabetes and obesity as well as certain constitutional diatheses. This volume also costs one franc. The third book is rather more expensive—in fact it costs as much as the other two put together It should be said, however, that the volume may be considered almost topical. "Inspired by the very suggestive title of M. de Brieux's play Dr X has taken for his title 'Conseils aux Avariés' and has produced a popular work of undoubted usefulness." We cannot pretend that lay opinion in England is at all well informed on questions of medical etiquette and it was recently the duty of THE LANCET to make the matter clear on one or two points. At the present time it seems that French physicians have even more reason than we have to take exception to some of the writing in the lay press of their country, for it is inconceivable that an article like the one from which we have quoted would be printed in the columns of a leading London journal.

SULPHUR IN RAIN SHOWERS

MORE than one observer in different parts of the country has volunteered the statement that the recent rains have left a deposit of sulphur on the earth and the conclusion has followed that this sulphur had its origin in the recent volcanic eruption in the West Indies. It is open to doubt whether the yellow deposit was due to sulphur at all, the probability being that it is the pollen of certain conifers. Assuming, however, that free sulphur was present its origin could not have been the dust showers of the West Indies eruption, for a recent analysis of the deposit collected from the deck of the steamer *Roddam* shows no free sulphur at all, but chiefly the silicates of alumina, iron, calcium, and magnesia. The only sulphur found was present as sulphate, and then only to the extent of less than 1 per cent The analysis, in short, shows that the dust possessed the composition of crude pumice.

THE MIDWIVES BILL.

ON Friday, June 13th, the Midwives Bill was read for a third time in the House of Commons after an interesting debate which will be found fully reported in our columns The amendment by which a woman uncertified under the Act is not only prevented from assuming the title of midwife but is also prevented from practising the habitual rôle of midwife for gain received the approval of the House though Mr Jesse Collings and Mr Ritchie both spoke against it. Mr Ritchie concluded the debate by defining his own position in the following terms "I prefer the Bill as it was originally, but I very much prefer the Bill as it stands now to not having any Bill at all.' After this statement it seems improbable that the Government will offer any resistance to the passage of the measure in the House of Lords.

THE NEW EXPEDITION OF THE LIVERPOOL SCHOOL OF TROPICAL MEDICINE.

DURING the researches of the last expedition of the Liverpool School of Tropical Medicine which visited the Gambia in the summer and autumn of 1901 an important discovery was made with regard to the animal parasite trypanosoma It was then discovered that the presence of this parasite in the blood is closely connected with disease in Europeans which had not previously been recognised It is very similar to the blood parasite which is the cause of the disease among cattle and horses in Africa, India, and other tropical countries, known as the tsetse fly disease. In the case of animals it has been proved that this disease is communicated through the agency of biting insects, such as the tsetse fly. The trypanosoma parasite was discovered in the blood of a native child. Since the return of the expedition the subject has been investigated at the laboratory of the Liverpool Tropical School and the committee of the school has resolved to despatch a fresh expedition to the Gambia and to Senegambia to follow up the investigation. The new expedition will start next month and will consist of Dr. J. E. Dutton, the Walter Myers Fellow in the Liverpool School of Tropical Medicine, and Dr. J. L. Todd of McGill University, Montreal, who has been working for some time in connexion with the Liverpool school. Its principal object will be to investigate the conditions under which the disease occurs in both Europeans and natives and its distribution, and also to ascertain how it is conveyed from man to man, whether by a biting insect or by other means. Sir Alfred L. Jones, K.C.M.G., the chairman of the school, will kindly provide for the passages of the members of the expedition.

[2] Le Figaro, June 13th

THE ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND.

THE committee of management of the Anatomical Society of Great Britain and Ireland has decided to hold the summer meeting at St. Bartholomew's Hospital Medical School, London, E.C., on Thursday and Friday, July 3rd and 4th, commencing each day at 3 P.M., under the presidency of Mr. C. B. Lockwood. The annual dinner of the society is arranged for Thursday, July 3rd, at the Café Royal, Regent-street, W., to commence at 7.30 P.M. Communications should be addressed to the honorary secretary, Dr. Peter Thompson, Middlesex Hospital, W.

THE VALUE OF BENEDIKT'S SYNDROME IN THE LOCALISATION OF LESIONS OF THE BRAIN.

SINCE Professor Benedikt of Vienna drew attention in 1889 to a group of symptoms, subsequently known as "Benedikt's syndrome," which occurred in lesions of the upper half of the cerebral peduncle, little has been recorded of this condition. Charcot, however, reported two cases in 1890 in which this group of symptoms was present and where the post-mortem findings confirmed the localisation of the lesion diagnosed during life. The symptoms which constitute Benedikt's syndrome are briefly a partial paralysis of the ocular muscles of one eye and a paresis of the opposite side of the body. In an article in the *Revue Neurologique* of May 15th last Dr. Leon d'Astros and Dr. E. Hawthorn have published a case illustrating the symptoms and diagnostic value of Benedikt's syndrome very clearly. The case was that of a child, aged 21 months, who was admitted to hospital in November, 1901, with oculo-motor paralysis of the right eye and paresis with involuntary movements of the left upper and lower limbs. The right eye remained closed sometimes for hours and could not at any time be fully opened. There were divergent strabismus and mydriasis of the pupil. There was also some spasmodic contracture of the left hand, including the thumb and fingers. The fore-arm remained in a state of semiflexion and pronation. The most salient feature, however, consisted of oscillations and rhythmic movements of the forearm which varied in amplitude and rapidity, occurring when the patient was awake and ceasing during sleep. The triceps tendon reflex was almost absent. The left leg lay extended and immobile with the toes semi-flexed but the foot showed rhythmic movements of extension of flexion. There was no Babinski symptom. The knee-jerks were exaggerated on both sides. Some degree of left-sided facial paralysis was present. The patient was anæmic and emaciated on admission and gradually grew worse and died on the nineteenth day. The necropsy showed a tuberculous tumour in the upper half of the cerebral peduncle, situated mainly to the right of the middle line. It was embedded in nerve-tissue and came nowhere into contact with the pia mater. Inferiorly it reached to within two millimetres of the upper border of the pons, and superiorly it extended to the ependyma of the third ventricle and involved the substantia nigra and subthalamic tissues. It measured 17 millimetres vertically and 16 millimetres transversely. Dorsally it reached as far as the iter and implicated the oculo-motor nucleus but spared the corpora quadrigemina. The clinical symptoms during life were so characteristic that diagnosis was made of a tumour in the above situation which the necropsy confirmed. A tumour in such a situation is beyond the reach of surgical operation, but the writers have shown that Benedikt's syndrome has a distinct diagnostic value.

THE PREVALENCE OF SMALL-POX.

THE figures showing the number of patients admitted to the hospitals of the Metropolitan Asylums Board for the past week are as follows:—On Saturday, June 14th, there were 18 fresh cases; on Sunday, the 15th, there were seven fresh cases; on Monday, the 16th, there were 12 fresh cases; on Tuesday, the 17th, there were 20 fresh cases; and on Wednesday, the 18th, there were eight fresh cases. In the county of Essex for the week ending June 14th there were notified 22 fresh cases, while throughout Scotland from June 1st to June 15th there were notified 41 fresh cases.

THE BREAD-SUPPLY OF JOHANNESBURG.

IN May last the chairman and members of the Public Health Committee of Johannesburg instructed Dr. C. Porter, the medical officer of health of that town, to inquire and to report in regard to the bread-supply and bakeries of Johannesburg. The report cannot be considered satisfactory; 85·7 per cent. of the bread sold was found to be appreciably under weight. It was also found to be deficient in quality; over 65 per cent. of the samples contained alum, many had an excess of acid, and others were sour and badly baked. The bakehouses generally were in fairly good structural condition and pretty well kept, but the ventilation of many was not worthy of praise and it was suggested that an improvement could be made by the adoption of louvred roof ventilators. The shallow-well water-supply of certain bakehouses was stated to be dangerous and a possible source of typhoid fever, and a recommendation was therefore made that every bakehouse should be supplied with water from the main or from an artesian well. In those houses where this plan could not at once be adopted Dr. Porter proposed that the water from the wells should be boiled and allowed to cool before being used for making dough. The attention of each baker in Johannesburg was ordered to be called to the results of this examination and the secretary of the water company was also communicated with. Now that peace is assured in South Africa the civil authorities will be able to supervise more closely the food- and water-supply, and doubtless the unsatisfactory state of affairs which existed in Johannesburg previously to May will speedily be remedied.

THE ANATOMY OF ANKYLOSTOMA DUODENALE.

IN the *Records of the Egyptian Government School of Medicine*, published in 1901 under the authority of the Egyptian Ministry of Public Instruction, Dr. A. Looss, professor of helminthology in the school, contributes an elaborate article on an important department of his special subject. This monograph, which fills 115 pages and is illustrated by 13 large plates containing 172 figures, is headed, "The Sclerostomidæ of Horses and Donkeys in Egypt." Its chief medical interest lies in the opening portion which is devoted to some questions connected with ankylostoma duodenale, a familiar designation which Dr. Looss says is no longer retained in modern zoological nomenclature but is replaced by the name "uncinaria duodenalis." It is generally conceded by those who are familiar with ankylostomiasis that the parasites in addition to sucking blood exercise a poisonous influence on the organism of the patient. It is also well known that the body of the parasite, and especially its anterior region, is provided with numerous large glands, distinguished as the head glands, neck glands, and œsophageal glands. Dr. Looss gives reasons for supposing that if the impairment of health which accompanies ankylostomiasis is really due to a substance secreted by the parasite this substance is probably derived from the head glands. In continuation of the research Dr. Looss turned his attention to sclerostoma, a parasite closely allied to ankylostoma and found in Egypt in immense numbers in the bodies of the equidæ. In examining the parasites he had much trouble from the tendency of their bodies to contract and to become wrinkled when they were removed from their natural habitat, but he overcame this difficulty by immersing them in alcohol of about 70 per cent. strength heated to 80° C.; they were then cleared in glycerine and mounted unstained in glycerine-gelatin.

THE ARMY MEDICAL ARRANGEMENTS FOR THE CORONATION.

The army medical arrangements in the metropolis in connexion with the processions on June 26th and June 27th have been made public and appear to be of a most detailed and comprehensive character. Stretcher squads will be stationed immediately behind the line of troops on either side of the route; 18 ambulance and six dressing stations will be established at convenient spots; and 10 field hospitals will be located at such varying points around the centre as Kensington Gardens, Hyde Park, St. James's Park, Battersea Park, Regent's Park, Lambeth Palace, Surrey Sessions House, Tower Ditch, King's College, and Hounslow Heath. The following seven general hospitals, the first four of which are actually on Friday's route, have engaged to reserve a certain number of beds for casualties of a severe nature occurring among the troops: St. Thomas's Hospital, St. George's Hospital, Charing Cross Hospital, Westminster Hospital, St. Bartholomew's Hospital, Guy's Hospital, and King's College Hospital. Special arrangements have been made for the Colonial and Indian contingents present in London for the ceremonies of the coronation. At Alexandra Palace temporary "non-dieted" hospitals have been established to meet the wants of over 3000 officers and men, while serious cases can be drafted to St. Thomas's Home (officers), Rochester-row Station Hospital (non-commissioned Europeans), and Herbert Hospital (non-commissioned natives). Field hospitals of 50 beds will be established in the Home Park, Hampton Court, and on Hounslow Heath; a detention hospital of 14 beds will be opened at Fulham Palace for the mounted troops of the Indian contingent; and a method is to be devised for the separate treatment of infectious diseases. The medical officers in charge of the various camps have been warned as to the need of the utmost vigilance against small-pox.

THE DISTRIBUTION OF PLAGUE.

The weekly return of the Director-General of the Sanitary Department of Egypt shows that for the week ending June 8th there were four new cases of plague admitted, of which one occurred in a European. There were two deaths, 14 recoveries, and 16 cases remained under treatment.

THE UNRESTRICTED SALE OF POISONS.

It is, of course, difficult to suggest a satisfactory system of control by which all poisons or poisonous preparations can be sold. Tobacco, paint, and alcohol are poisons, but there is practically no limit to their sale. Whilst admitting, however, the danger to the community which the unrestricted sale of poisonous compounds intended exclusively for agricultural purposes would possibly involve it is pretty evident that the provisions of the Pharmacy Act were never intended to apply to such preparations. The sale, for instance, of a weed-killer or insecticide does not surely require the offices of a particularly well-educated or qualified person, such as is the chemist and druggist. The chemist and druggist is required to possess an accurate knowledge of poisons for obvious reasons, chief amongst which is that he dispenses them for internal administration. Elsewhere we record a case in which a seed and artificial manure merchant was summoned for selling a poisonous vegetable alkaloid known as nicotine without having his name and address on the bottle, and for selling the poison to an unknown person, and for failing to make an entry of the sale in a book kept for the purpose, contrary to the provisions of the Pharmacy Act, 1868. The preparation was sold as a "vaporiser fumigator" which is used for the destruction of greenhouse pests. Evidence was given to the effect that the compound contained over 20 per cent. of nicotine, two ounces containing as much as 186 grains of the alkaloid—a quantity, it was stated, sufficient to prove fatal to at least 300 persons. The case was considered proved and the defendant was fined £2 on each of the three summonses, including costs. Consent, however, was given to state a special case for the Court of Appeal. Instances of this sort are multiplying and it is to be hoped that the Privy Council Poisons Committee may find that they will be able to control the sale of poisons in some way which, while duly protecting the public, will not threaten to extinguish an undoubtedly important trade. We learn that the report of this committee is not expected until the end of the autumn. Their decision will have an important bearing upon the case which we have just discussed.

THE SMOKE NUISANCE IN NEW YORK.

A very instructive incident is reported in our columns this week by our New York correspondent in regard to the smoke nuisance which has recently arisen in that city. As is well known, the fuel used for heating purposes in New York, as in most continental cities, is anthracite. As a consequence the atmosphere of these cities is never blackened with smoke, for anthracite is a smokeless fuel. Owing, however, to the high price of hard coal in New York city, as a result of the general strike amongst the anthracite colliers cheaper and smoky coal has suddenly come into vogue. This change of fuel soon had its bad effect upon the atmosphere of the city and to some extent the inhabitants have been experiencing a condition of things similar to that frequently met with in London, where the householders are allowed to pollute the air with comparative impunity. In New York city it is a civil offence for a householder to allow smoke other than white, or cinders, dust, gas, or any offensive odour to come from his chimney. We fear that it would be impossible to impose such a restriction as that regarding the use of anthracite or smokeless coal in London. But what an excellent result would accrue could it be done. There is little doubt that the householders of the metropolis tarnish the atmosphere of London to an infinitely greater degree than does the manufacturer. There is no reason, however, why pressure should not be kept to bear upon the latter offender. It is quite easy to prevent smoke-production in a large furnace even when soft bituminous coal is used, whereby not only is a nuisance effectually checked but an important economy of fuel obtained, as we have repeatedly pointed out. In New York notice is to be sent to all persons guilty of the offence to discontinue the use of soft coal within five days and in aggravated cases within 24 hours. If the notice is not complied with prosecution is to be immediately instituted and in case of the smoke blowing into neighbouring windows the offenders will be brought to book on a criminal charge. It is a thousand pities that the use of anthracite or smokeless coal cannot be compelled in the private dwelling-houses of London and of this country. But London and smoke are accepted by a great many as synonymous terms and not a few on grounds of sentiment would object to having this acceptation disturbed.

A WORK OF REFERENCE ON THE PUBLIC HEALTH ACTS.

LEGISLATION affecting the very wide subject of sanitary affairs has been so abundant during recent years as to render a precise acquaintance with all the Acts relating at the present time to public health somewhat laborious to acquire. The recent issue from the press of "Lumley's Public Health" in two volumes will therefore be welcomed.[1] The fifth edition was published early in 1896 and since that date many important amendments and additions have been made to the statutes concerning public health administration. In this connexion may be mentioned the amendment of the Local Government Act in May, 1896; the amendment in the Public Health Act in August of the same year as regards diseases on incoming ships and as to ports; the compulsory notification of infectious diseases in June, 1899; and the important amendments in the Housing of the Working Classes Act, 1890, in August, 1900. Furthermore, new Acts have come into operation—namely, the Locomotives Act, 1898; the Electric Lighting Clauses Act, 1899; the Sale of Food and Drugs Act, 1899; and the Factory and Workshop Act, 1901. The work, again, is invaluable in presenting typical cases that have been decided in quite recent times upon points arising under the old as well as under the new statutes. The index is very thoroughly done and altogether the two volumes are of the utmost value in facilitating the task of reference and in placing before those who consult the sections the requirements, meaning, and acceptation of the laws relating to public health.

THE Honourable Stephen Coleridge brought an action in the King's Bench Division before Mr Justice Grantham on Wednesday last to recover damages from the Rev David Macdonald for alleged libels published in the *Derby Express* and the *Derby Daily Telegraph*. Mr. Macdonald admitted the publication of the letters complained of, which contained, among other things, the phrase that "lovers of animals and lovers of truth will have nothing to do with his (Mr. Coleridge's) society." The jury stopped the case, being unanimously unable to see anything libellous in Mr. Macdonald's letters, a view with which the judge agreed.

THE annual provincial meeting of the Incorporated Society of Medical Officers of Health will be held on Saturday, June 28th, in the Council Chamber, Southend-on-Sea, at 12 noon. An address will be given by Dr. J. T. C. Nash on Matters of Public Health Interest in Southend.

LITERARY INTELLIGENCE.—A German translation of Dr. Charlton Bastian's "Treatise on Aphasia and other Speech Defects," by Dr. Moritz Urstein of Berlin, has just been issued by W. Engelmann of Leipsic.

THE METROPOLITAN WATER-SUPPLY: THE LONDON WATER BILL.

LORD BALFOUR of BURLEIGH presided over the meeting the Joint Committee which was held on June 10th. Th numbers and composition of the proposed Water Board we considered. The representation of authorities on the boa as proposed in the Government measure is given in th third schedule of the Bill. In this schedule it was provide that the London County Council should have 10 representativ and the county councils of Essex, Kent, Middlesex, Surre Hertfordshire, the Conservators of the river Thames, and th Lee Conservancy Board one member each. The councils the cities of London and Westminster and the metropolit borough councils of Islington, Kensington, Lambeth, S Pancras, and Stepney were to have two representatives eac and the other metropolitan boroughs one member each. the county of Essex the borough of West Ham was to have tw representatives, and each of four large urban districts o member each. In Kent two urban districts were to have o member each; in Middlesex four and in Surrey two lar districts were to have one member each.

The time of the Committee was chiefly occupied in hearin evidence and arguments on a proposal of the London County Council, the object of which briefly was to diminish the number of representatives allotted to other authorities and to increase the number allotted to itself, so that it might control the whole business.

The first proposal of the London County Council was that the number of representatives on the Water Board should be reduced to 29.

SIR B. T. LEECH, an alderman of Manchester and deputy chairman of the Water Committee of that city, said that the water-supply of Manchester was managed by a committee of 18 members and that he was convinced that a board of 69 members was too large; he also gave it as his opinion that the London County Council should have the control of the water-supply.

MR. W. ANDERSON, treasurer of the Edinburgh Water Trust, said that the number of the Edinburgh trustees was 25 and he thought that a managing body should not be too numerous.

One of the deputy town clerks of Glasgow gave evidence to the effect that the city of Glasgow comprised an area of $12\frac{1}{2}$ square miles; the total area of the water supply was 87 square miles, and the boroughs outside Glasgow had no representation on the committee. The Government Bill, he thought, would constitute an unwieldy body (It may be worth while to note, without going into detail in the matter, that the events which led to the possession of their water-supply by the city of Glasgow have no counterpart in the history of the present London water-supply. And this fact must be well known to those responsible for the "case" presented by the London County Council.)

MR. BRYAN, engineer to the East London Waterworks Company, gave it as his opinion that every municipality ought to be represented on the Water Board. Members of the municipal councils had given valuable assistance to the East London Company in times of drought. He thought, having regard to the amount of administrative work which the water-supply necessarily entailed that the number of members provided for in the Government Bill was not excessive because the details of the work of management would have to be delegated to committees.

On behalf of the Local Government Board MR. FITZGERALD, K.C., said that the Mayors of Stepney, of Holborn, of Kensington, and of Hammersmith wished to have an opportunity of stating their views in favour of the Bill as drawn, but he did not think it necessary to call them as witnesses. The Bill was also supported by counsel who represented respectively the city of Westminster, the council of the urban district of East Ham, the county councils of Middlesex, of Hertfordshire, and of Essex, and the urban districts of Hornsey and of Wimbledon.

On behalf of the London County Council MR. BALFOUR BROWNE, K.C., suggested that the amendment proposed by that body would lead to the constitution of a Water Board like that proposed by Lord James of Hereford (Metropolitan Counties Water Board Bill, March, 1898).

Of the two amendments introduced by the London County Council the first, which proposed that 29 instead of 67 epresentatives should sit on the Water Board, provided at the members elected should be allocated as follows: ondon County Council, 16; the City of London, the orough of West Ham and the county councils of Essex and f Middlesex, two each; the county councils of Kent, of urrey, and of Hertfordshire, the Conservators of the Thames, nd the Lee Conservancy Board, one each. The second mendment, introduced in case the first was not adopted nd which *made provision for the election of 33 representatives*, proposed that they should be allotted somewhat ifferently. Two additional members each were to be given the county councils of Kent, of Middlesex, and of Surrey, nd two less to the County Council of London.

---

[1] The Public Health Acts, annotated with appendices, first edition, by W. G. Lumley, LL.M., Q.C., and Edmund Lumley, B.A., sixth edition, by Alexander Macmorran, M.A., and S. G. Lushington, M.A., B.C.L. London Shaw and Sons. 1902. Two volumes, pp 1710. Price £3 12*s*. 6*d*. and £2 19*s*. 3*d* respectively.

Mr. **WEDDERBURN**, K.C., on behalf of the Kent County ouncil, supported the Government Bill.

Mr. **BLENNERHASSETT**, K.C., on behalf of the City of estminster, protested against the attempt which had been ade to deprive that city and the metropolitan boroughs of he representatives which had been allotted to them.

Mr. FITZGERALD, on behalf of the Local Government oard, insisted that it was impossible to force five or six ounties into a board dominated by the London County ouncil.

The Committee decided unanimously to reject the proposal reduce the number of members on the board to 29, and ey further decided on an equality of votes not to reduce e number to 33. An amendment proposed by a member the Committee to increase the number of representatives the *London County Council from* 10 *to* 16 *was lost* by 7 tes to 3. The Committee likewise declined to advise any crease *to the number (two) of representatives allotted to* e City of Westminster.

At the sitting of the Joint Committee which was held on une 11th Lord **BALFOUR** of **BURLEIGH** again presided.

Mr. BAGGALLAY, K.C., on behalf of the Conservators of e river Thames, asked that the number of members ssigned to the board should be increased to three and that should not be prescribed that distinctive representation ould be given to the upper part of the river.

Sir F. **DIXON HARTLAND**, chairman of the Thames Conservancy Board, said that there was no antagonism between e interests of the lower and upper parts of the river and at the board, as a whole, was strongly of opinion that e value of the additional representation which it claimed ould in great measure be lost should specialised representation be made in the way suggested.

The Committee amended the schedule by adding two presentatives to the Thames Conservators but with the roviso that one shall represent the upper districts of the ver. The schedule was further amended by the addition one member to the urban district of Tottenham and one the urban district of Hornsey. In consequence of these dditional members the total number of the members of the ater Board was increased from 67 to 71.

Lord **BALFOUR** of **BURLEIGH** announced that the schedule amended would stand as part of the Bill and that a pecial report would be made by the Committee as to the ode of procedure by which its decision had been made.

The Committee *having settled the schedule returned to* onsider Clause 11 of the Bill. This clause deals with the ay in which the expenses of the Board are to be met and he manner in which the necessary money is to be raised in ase the water rents are insufficient for the required purpose. t was proposed by the London County Council that in order provide for such a deficiency a rate should be levied in ondon and in such of the extra-metropolitan urban and ral districts as are within the limits of the water-supply. his amendment was lost on "an equality of votes."

The Local Government Board, in order to conform with the ishes of the Corporation of the City of Westminster, proosed a provision to the effect that no reduction in the water ents at present in force should be made if such a reduction ould, or would be likely to, cause a deficiency in the water und.

The Committee *accepted* this amendment.

DONATIONS AND BEQUESTS.—The treasurers of he Middlesex Hospital have received from Mr. Timothy Bean further sum of one thousand guineas for the purpose of ndowing another bed in the cancer wing, to be known as the "Rebecca Bean" bed; also a further grant of *£500 from* the rustees of the Smith's (Kensington Estate) Charity to the eneral fund.

METROPOLITAN HOSPITAL SUNDAY FUND.

THE following is a record of some of the principal amounts that have been received in aid of the Fund up to the time of going to press on Thursday. The total sum then amounted *to £20,000.* At the corresponding period last year the total was £25,000; but this included a donation of £10,000 from Mr. George Herring, who has not yet, of course, been able to add his generous offer of 5*s.* in the £1 on all amounts collected in the various churches and chapels. The sum collected to date is, therefore, most encouraging.

ANNUAL DINNER OF THE INDIAN MEDICAL SERVICE.

THE annual dinner of the Indian Medical Service was held at the Café Monico, Piccadilly-circus, London, on Thursday, June 12th, Dr. W. S. PLAYFAIR occupying the chair.

After the usual loyal toasts had been felicitously proposed by the CHAIRMAN and heartily received "The Sister Services" was proposed by Surgeon-General A. C. C. DE RENZY, C.B., and responded to by Surgeon-General W. TAYLOR, C.B., Director-General of the Army Medical Service

Surgeon-General Sir JOSEPH FAYRER, Bart., K.C.S.I., F.R.S., in submitting "The Guests" briefly alluded to the great services rendered by the President of the Royal College of Physicians, Sir William Church, to medicine in general and more particularly to his work as a member of the Royal Commission appointed to inquire into the charges made against the medical services in the recent war in South Africa; he then read the concluding words of the report of the Royal Commission with which our readers are familiar but as they will bear repeating we reproduce them. "But in concluding our report we desire to say that in our judgment, reviewing the campaign as a whole, it has not been one where it can properly be said that the medical and hospital arrangements have broken down. There has been nothing in the nature of a scandal with regard to the care of the sick and wounded; no general or widespread neglect of patients or indifference to their suffering. And all witnesses of experience in other wars are practically unanimous in the view that, taking it all in all, in no campaign have the sick and wounded been so well looked after as they have in this" In proceeding to congratulate Surgeon-General Taylor, the Director-General of the Royal Army Medical Corps, on his appointment to that high office "we wish," Sir J. Fayrer said, "to express our satisfaction that the choice of Government should have fallen on one so well fitted to perform its duties. It is now charged with greater powers and higher responsibilities, with higher rank, more fitting remuneration, and a place more befitting its importance in the councils of the War Office, and one in which, if the spirit as well as the letter of the new rules be observed, the opportunities of doing good will be infinitely enhanced. We anticipate with much confidence the best results from Surgeon-General Taylor's appointment and we offer him our best wishes with our hearty congratulations." Sir J. Fayrer also bore testimony to the scientific work and personal worth of Sir T. Lauder Brunton and Dr. W. H. Allchin and to the aid that was always given to the medical services by the editors of the medical journals.

Sir WILLIAM CHURCH replied and in concluding his speech remarked that he was perfectly certain that every one of the Royal Commissioners who signed the report most earnestly meant every word that he said

"The Indian Medical Service" was given by the CHAIRMAN who said that he had not the slightest doubt that many present were saying, "Who on earth is this man and by what possible right does he represent the Indian Medical Service?" To such he might say that he thoroughly agreed with them and nothing but the kind insistence of their committee could have persuaded him to fill a position for which he felt that he had no qualification. Just 42 years had elapsed since he, a young and obscure assistant-surgeon, had to leave India from ill-health after only three years' service, with something like despair in his heart at having to abandon what he had mapped out for himself as the career of his life. Luckily, like others similarly situated, he had his profession to fall back on. He was told that the best opening then was in "obstetric medicine." The difficulty was that he practically did not know what "obstetric medicine" was. He adopted the plan taken by the literary hack who had to write an article on "Chinese Metaphysics," who read up "China" and then read up "Metaphysics" and combined his information. So he read up "Obstetrics" and then read up "Medicine" and combined this information and on that combined information he had managed to subsist ever since. One qualification for his position to-night he possessed in a degree excelled by no man, that was a profound regard for the grand old service represented to-night, which had been in the past the finest public medical service which ever existed and which he did not doubt would continue to be so in the future. After further remarks the Chairman dwelt on the great loss the service had experienced in the death of its director-general—Surgeon-General Harvey—who was in the chair last year. After dwelling on his career he expressed the conviction that his memory would always be held dear by the service over which he presided.

The health of "The Chairman" was proposed by Deputy Surgeon-General H. CAYLEY, C.M.G., and Dr. PLAYFAIR replied.

A very pleasant evening concluded with an expression of thanks to Colonel P. J. Freyer for the successful results of his labours as honorary secretary of the dinner.

The following is a list of the officers and guests present:—

Surgeon-Generals: W. W. Beatson, A. C. De Renzy, C.B., Sir Joseph Fayrer, Bart., K.C.S.I., F.R.S., W. R. Hooper, C.S.I., W. R. Rice, C.S.I., C. Sibthorpe, C.B., and P. W. Sutherland. *Colonels:* W. E. Cates, H. Cayley, C.M.G., D. E. Hughes, B Williamson, and W. A. S. Wynne. *Lieutenant-Colonels:* M. L. Bartholomeusz, A. Crombie, P. J. Freyer, G. H. D. Gimlette, P. de H. Haig, H. N. V. Harington, G. F. A. Harris, D. F. Keegan, W. A. Lee, I. B. Lyon, C.I.E., D. P. MacDonald, R. Macrae, J. Parker, J. Reid, T. G. Skardon, W. H. Thornhill, J. F. Tuohy, and A. H. Williams *Majors:* A. W. Alcock, E. H. Brown, W. S. Caldwell, G. Giffard, P. C. H. Strickland, and J. L. T. Jones. *Captains:* H. M. Earle, F. A. L. Hammond, S. A. Harriss, W. D. Hayward, J. G. Hulbert, E. C. McLeod, C. Milne, A. E. Hayward Pinch, and G. Tate.

Guests: Sir William Church, Bart., President of the Royal College of Physicians of London; Sir T. Lauder Brunton; Surgeon-General W. Taylor, C.B., Director-General A.M.S.; Dr. W. H. Allchin, President of the Medical Society; Dr. Dawson Williams; and Mr. Thomas Wakley, jun.

ANNUAL DINNER OF THE ROYAL ARMY MEDICAL CORPS.

THIS dinner was held on Monday, June 16th, in the Whitehall Rooms of the Hôtel Métropole, London. At the conclusion of the dinner Surgeon-General W. TAYLOR, C.B., Director-General, who occupied the chair, proposed the toast of "The King," remarking that they were all glad to think that the indisposition from which His Majesty was suffering was not of a serious nature. He then proposed the health of "The Queen, the Prince and the Princess of Wales, and the rest of the Royal Family." Her Majesty was, he said, more closely connected with them than had any sovereign been in days gone by, seeing that she had graciously consented to act as president of their nursing board. These were the only toasts on the programme but Surgeon-General Taylor, rising again, said he thought it right to ask them to drink the health of one who as honorary secretary of the annual dinners on many previous occasions had done much to add to their comfort—he alluded to Lieutenant-Colonel J. Hector, to whom he was sure they would admit that they were all deeply indebted. This toast was received with much applause and musical honours and Lieutenant Colonel HECTOR briefly responded. We must not omit to mention that in the reception-room, where the company gathered previously to the dinner, there was exhibited a portrait in oils of the late Director-General, Surgeon General J. Jameson, C.B. This portrait was a replica of the one by Mr. W. R. Symons which is now being exhibited at the Royal Academy and is to be presented to Surgeon-General Jameson by his brother officers. The dinner was very well attended and a most agreeable evening was spent, much credit being due to the officer who has so worthily succeeded Lieutenant-Colonel Hector in the discharge of the duties of honorary secretary—Lieutenant-Colonel E M. Wilson, C.M.G, D.S.O. The following is a list of those present:—

Honorary Members.—Mr. A. D. Fripp, C.B., C.V.O., Dr. J. Galloway, and Dr. E. C. Perry.

Members.—*Surgeon-Generals:* A. F. Bradshaw, C.B., Sir J. H. K. Innes, K.C.B., K.H.S., A. H. Keogh, C.B., T. Maunsell, C.B., H. S. Muir, C.B., A. F. Preston, K.H.P., J. B. C. Reade, C.B., K.H.S., P. B. Smith, W. Taylor, C.B., K.H.P., and J. Warren. *Deputy-Surgeon-Generals:* O. Codrington and J. H. Jeffcoat.

evidence of the third case having partaken of that milk." Dr. Ballard makes the following interesting observation :—

"*What is to be gathered from coincidences?*—In an inquiry into an epidemic such as this, where the cases of the disease are distributed about a district having certain common features, there are four sources which are ordinarily looked to as those whence the contagium of the disease is most likely to have proceeded and by the medium of which it may have been distributed, viz. : (1) a common source of water-supply, such as some particular well or stream or the mains of a system of public supply, in which case infection of the water, either at its source or in its progress for distribution, may result in the distribution with it of an infective material; (2) a common system of drainage, in which case a sewer becoming infected may be the means of distributing, through the medium of the sewer air, infective matter to the houses in relation with such sewer; (3) where there is no common water-supply and no common system of drainage to account for a wide distribution of fever, the cause of the spread may be found in the progressive infection of independent privies, &c., and by soakage from them into independent wells or other supplies of drinking-water; or (4) the cause of the spread may be found in the distribution over the district of some particular article of food, such as milk, which has become infected."

Dr. Ballard then shows that the first three sources were not operating in this case, but that the fourth was, almost all the families infected being supplied with milk from a farm known as the Brick-kiln farm, and he comes to the following conclusion : "The facts which I have detailed can leave, I think, no doubt upon the mind that the use of milk distributed from Brick-kiln farm was in some way directly associated, as cause with effect, with the distribution of *enteric fever through the Ascot and Sunninghill districts* during the long period of four and a half years.[2] It is no valid objection to this inference to say that many families to which this milk was distributed have hitherto escaped invasion, and that a few families which used milk from other sources suffered similarly from fever. The obvious reply to the first of these objections is that in no milk epidemic hitherto investigated *has more than a fraction (although* usually a large fraction) of the families using the infected milk been invaded; and to the second objection that the operation of one predominating cause of an epidemic of fever by no means precludes the operation of other causes concurrently existent." After describing the premises he adds: "The above account of the condition in which I found the farm and dairy premises, and of the slovenly arrangements under which the business was conducted, indicates more than one way in which the milk might have become befouled. It is obvious that the cans in which the milk was sent out were liable every day or any day to befoulment even during the process of cleansing. The water used for rinsing the cans was a dangerous water to use for the reasons just assigned, being doubly liable to befoulment—namely, first, from the soakage of foul matters into the well from privies and the manure heap, and, secondly, from the absorption of the foul emanations from the drains which communicated with the pump case. After rinsing they were again liable to befoulment from drain emanations rising through the sink pipe over which they were sometimes inverted to drain. And, finally, the milk itself might at any time have become befouled by standing in the room into which the sink pipe opened. In addition to all which the brush used in cleansing the cans and the rags used for the same purpose, or for plugging the pump spouts, might, from their constant vicinity to the sink pipe, have become fouled by the drain emanations and thus have become a medium by which those filthy emanations might have been conveyed to cans. With respect to the open cistern within the pump case I may point out that its circumstances were similar *in all essential points* to those of the water cisterns in many London houses, where the waste-pipe opening above into the space between the water and the cistern cover is continued without any break or intervening trap into the house drain, and is liable to carry up sewer-air into that interval, whence it may be absorbed by the water. There is abundant evidence to show that enteric fever has, in London, been frequently caused by the use of *cistern water stored under such conditions*. I have specially mentioned the circumstances under which the water used may have introduced a filth pollution into the milk by merely rinsing the cans with it, because former experience of milk epidemics of fever have demonstrated that given an infected water the small quantity of such water which may hang about a milk-can after rinsing with it is amply sufficient to infect the milk subsequently put in. The infection of milk by an infected water by no means implies fraudulent dilution of the milk with that water, of which, moreover, there is no evidence in this instance. To all this I may add that there is an accidental way in which filth may gain access to milk, which must never be overlooked,—namely, from the hands of the milker." He then asks: "*Had the 'filth' that had access to the milk any opportunity of receiving specific infection?*—This is a further question some attempt to answer which will be expected by those who subscribe to the doctrine that (putting mere possibilities aside as not matters of scientific argument) enteric fever contagium as we now meet with it has an ancestry; and however long and widely and through whatever media it may have travelled about prior to finding a lodgment suitable for its development in a human system, that it or its ancestor at one time issued with excremental matter from some individual affected with the disease. It is a doctrine which I myself provisionally accept as most in accord with my own experience and also, so far as I have been able to judge, with that of the most competent and, let me add, most patient observers. With such as dissent from it I can agree in admitting that there is very much in the natural history of contagium in general, and of enteric fever contagium in particular, wrapt in an obscurity yet unpenetrated; but I am hopeful enough to look forward to the time when the advance of scientific inquiry will render that clear which is now dark."

Lastly, he made investigations on this important point and came to the conclusion "that there were various opportunities for the 'filth' thus introduced into the milk to become specifically infected with the infective matter of enteric fever." It is interesting to note that in the specification of works to be done at this dairy a brick dipstone trap (now quite obsolete) is specified and a sketch of it is given.

An outbreak at St. Albans *in 1884, investigated first by Dr.* O. E. Saunders, the medical officer of health, and afterwards by Mr Shirley Murphy for the Local Government Board.—This was a simultaneous outbreak of typhoid fever in St. Albans and in London among the consumers of milk coming from a farm near the former city. Although the disease was undoubtedly traced to the milk, which must have been contaminated, there was an absence of evidence that the milk at the farm had become infected in any of the commonly believed ways, but there was "some reason for believing that the milk from this farm, which had in the summer of 1883 given rise to a serious outbreak of enteric fever in St. Pancras, had retained, although to a slight degree, power of infecting its customers in the interval between the two outbreaks." The great interest and importance of this conclusion are obvious.

Dr. Airy reported in 1885 that there was a severe outbreak of typhoid fever at Lower Sherringham (Norfolk) under circumstances pointing to contamination of milk-supply, but that the origin of the infection was uncertain.

Mr. Harvey reported in 1888 that epidemic typhoid fever at Swanage (Dorset) was "associated at its commencement with the use of milk from a dairy situated on the *polluted brook and without water-supply on the premises*."

In 1886 Dr. J. Ashburton Thompson, then an inspector under the Board of Health of New South Wales, presented a report on an outbreak of typhoid fever in the municipal district of Leichhardt, which he had traced to polluted milk and in which he draws the following conclusion as to the cause of the outbreak "All possible causes have now in turn been examined. It has been shown that its attack and decline were alike *sudden; that it occurred at a time when* the district affected by it was practically free from fever; and that it was almost entirely confined to customers of a particular dairy, cases of fever among others than customers being very few, and two having had ample opportunity at least of sharing the milk. It has been shown further that those customers lived under general conditions which were equally shared by all the inhabitants of the district, their number being *615 and against very nearly 10,000* who were not customers. It has been shown, therefore, that the condition common to the persons attacked must have been one to which the persons who escaped were not subject; and that the only condition answering to this requirement is the

---

[2] The low fatality which has attended the epidemic corresponds also with experience as to other epidemics of enteric fever due to milk, only two persons out of the 69 died.

Brigade-Surgeons: C. Mackinnon and T. W. Wright. *Colonels:* W. L. Gubbins, G. D. N. Leake, T. Ligertwood, W. T. Martin, J. Maturin, J. Macnamara, R. H. Quill, F. B. Scott, C.M.G., and W. F. Stevenson, C.B. *Lieutenant-Colonels:* J. Anderson, C.I.E., W. Babtie, V.C., C.M.G., H. L. Battersby, J. F. Beattie, U. J. Bourke, A. L. Browne, D. Bruce, S. H. Carter, Sir J. R. A. Clark, Bart., T. M. Corker, A. B. Cottell, J. J. Crean, A. M. Davies, J. R. Dodd, W. G. Don, P. M. Ellis, E. H. Fenn, C.I.E., M. M. Gallwey, F. A. Harris, H. G. Hathaway, L. Haywood, J. Hector, F. H. Hensman, C.M.G., R. D. Hodson, F. Howard, H. W. Hubbard, H. E. R. James, R. Jennings, J. W. Jerome, W. Johnston, W. Keir, H. O. Kirkpatrick, J. Macartney, J. W. Morgan, J. E. Nicholson, E. North, H. J. O'Brien, W. W. Pope, S. K. Ray, J. H. Reynolds, V.C., W. F. Rutledge, W. Temple, V.C., F. H. Treherne, G. T. Trewman, P. B. Tuthill, E. O. Wight, and E. M. Wilson, C.M.G., D.S.O. *Majors:* H. A. Cummins, C.M.G., A. Dodd, W. L. Gray, F. J. Greig, J. Hickman, T. McCulloch, W. G. Macpherson, A. H. Morgan, D.S.O., J. C. Morgan, J. D. T. Reckitt, B. H. Scott, B. M. Skinner, G. J. A. Tuke, L. Way, and M. T. Yarr. *Surgeon-Majors:* C. R. Kilkelly, C.M.G., and Allan Perry. *Captains:* C. W. Duggan, R. S. H. Fuhr, D.S.O., A. F. Heaton, E. T. Inkson, V.C., A. Pearse, C. T. Samman, and E. McK. Williams. *Lieutenants:* T. Biggam, L. Cotterill, B. A. Craig, H. E. M. Douglas, V.C., D.S.O., T. B. Unwin, and J. H. R. Winder.

Guests.—Surgeon General W. R. Hooper, C.S.I., Indian Medical Service, Mr. Vesey Holt, Mr. Thomas Wakley, jun., and Dr. Dawson Williams.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

An ordinary meeting of the Council was held on June 12th, Mr. HENRY G. HOWSE, the President, being in the chair.

It was resolved to lend to the University of London specimens from the museum during the year 1902, subject to the University agreeing to pay any expenses connected with the removal of the specimens from one institution to the other and any damage that might be occasioned to the specimens.

The Council elected the following examiners:—

Elementary Biology.—Herbert Willoughby Lyle, Peter Chalmers Mitchell, Frederick Gymer Parsons, and Walter G. Ridewood.

Anatomy (under the Conjoint Examining Board).—Christopher Addison, Arthur Keith, Arthur Thomson, and Holburt Jacob Waring.

Physiology (under the Conjoint Examining Board).—Thomas Gregor Brodie, George Alfred Buckmaster, and William Henry Thompson.

Anatomy (for the Fellowship).—James Ernest Lane, Berkeley G. A. Moynihan, Frederick Gymer Parsons, and Alfred Harry Young.

Physiology (for the Fellowship).—De Burgh Birch, Leonard Erskine Hill, Edward Waymouth Reid, and Ernest Henry Starling.

Midwifery (under the Conjoint Examining Board).—George Francis Blacker, William Radford Dakin, William Duncan, and James Henry Targett.

For the Diploma in Public Health.—Part 1.—Alexander Grant Russell Foulerton. *Part 2.*—Sydney Arthur Monckton Copeman.

A letter was read from Mr. Morton Smale resigning his seat on the Board of Examiners in Dental Surgery. Mr. Morton Smale's resignation was accepted and the Council expressed their appreciation of his services during the time he was on the Board, and the PRESIDENT stated that the vacancy so occasioned would be filled up at the ordinary meeting of the Council following the quarterly meeting in July.

A letter was read from Mr. A. Hopewell Smith, honorary secretary of the Odontological Society of Great Britain, reporting that at the last meeting of the Council of the society a vote of thanks was accorded to the Council of the College for storing the museum specimens of the society during the removal of the institution from Leicester-square to Hanover-square.

A letter was read from Mr. Thomas Bryant reporting the proceedings of the General Medical Council at the late session. The best thanks of the Council were given to Mr. Bryant for his services as the representative of the College in the General Medical Council.

In response to a request from the President of the Royal College of Physicians of London the Council nominated the President, Mr. H. G. Howse, as a member of a committee to be appointed for the purpose of preparing a revised edition of the "Nomenclature of Diseases."

July 8th was appointed as the day for receiving a deputation from the Association of Licentiates of the Royal College of Physicians of London and Members of the Royal College of Surgeons of England with a petition to the Council. The petition asks that the Royal Colleges will assist the petitioners in obtaining the privilege of offering themselves as candidates for the final examination for a degree in medicine at a British university or in some other way removing the disability under which they labour of being unable to style themselves "Doctor."

It was resolved to ask the Royal College of Physicians of London to appoint a committee to act in conjunction with a committee of the Council in order to decide whether or not any practicable scheme can be devised for entering into combination with the University of London for the adoption of a system of common examination for the M.B. degree of the University and the diplomas of Licentiate of the Royal College of Physicians of London and of Member of the Royal College of Surgeons of England.

THE REORGANISATION OF THE BRITISH MEDICAL ASSOCIATION.

An extraordinary general meeting of the members of the British Medical Association was held at Exeter Hall on June 18th, at which 124 were present. By three votes in excess of the necessary three-quarters majority the new regulations for the Association were adopted. A further extraordinary general meeting, however, will have to be held on July 9th to confirm what has been done.

The chairman of the meeting was Dr. G. B. FERGUSON of Cheltenham, the President of the Association, who pointed out that the scheme of reorganisation of the Association had been discussed for two years. Many meetings had been held to consider it and at least £1000 of the money of the Association had been expended upon it. In his opinion there was nothing particularly revolutionary in the scheme, though the Council would no longer be able to disregard the findings of annual representative meetings.

Mr. EDMUND OWEN, in the course of his remarks, said that the feeling of dissatisfaction with the Association as previously constituted was very widely spread in the ranks of the profession. It had been said that the scheme of reorganisation of the Association was intended to revolutionise the condition of affairs. The word "revolution" meant an entire change in the government and that was exactly what was intended to be effected in the Association. They must accept the scheme as it stood because it was like a stone arch—if one of the stones was pulled out the whole would give way.

Mr. ANDREW CLARK believed that the scheme would revolutionise the Association in a way that everyone would wish. It certainly could not be called a hole-and-corner scheme and it could not be said to be either hurried or ill-drawn. It could be accurately described as a give-and-take arrangement between the reformers and those who were opposed to change. Much objection had been raised to the plan of cumulative voting, but if it was found that that did not work it could be altered in three months' time.

Dr. J. BRASSEY BRIERLEY, who experienced a mixed reception, criticised the scheme from a financial point of view and said that the annual meetings of the branches were mere picnics. The proposed representative meetings were altogether out of touch with modern thought. Dr. Brierley concluded by saying that the scheme had been passed at the Cheltenham meeting, but there was such a charming atmosphere of hospitality there that the members would have passed anything; he believed they would even have stood on their heads if told to do so.

Mr. GARRETT HORDER thought that the Association would be carried on better if the council were to make more business-like arrangements for the annual meeting. The proposed scheme was a leap in the dark and he was afraid that it would a very fatal leap.

Dr. J. WARD COUSINS emphasised the point that the 124 members at the meeting were acting for nearly 19,000 gentlemen. He thought that the scheme would dislocate the vital centre of the Association and that the spirit of trade-unionism pervading the scheme was unworthy of a liberal profession.

Dr. A. COX of Gateshead and Mr. J. S. WHITAKER made speeches which were well received in favour of adopting the proposed scheme.

After Mr. Whitaker's remarks the meeting wished to proceed at once to voting; Dr. FERGUSON, however, persuaded them first to hear a few words from Dr. LORIMER HART who promised to be brief. There was some confusion in regard to the result of the voting until a poll was demanded, and the exact figures of 28 against the scheme and 96 for the scheme definitely cleared up the question whether the necessary three-quarters majority of those voting had been secured.

THE SECOND ANNUAL CONVERSAZIONE OF THE ROYAL SOCIETY.

Contrary to expectation raised by coming coronation festivities and the presence of many august visitors in London the second annual conversazione of the Royal Society, held at Burlington House on June 18th, was decidedly dull from the point of view of exhibits. The company, however, was perhaps the most brilliant ever gathered together in the Royal Society's rooms. Quite two-thirds of the exhibits had been previously shown on "black night," as the first conversazione is called from the fact that only gentlemen are present, while at the second demonstration the Fellows are invited to bring ladies.

We need, therefore, not repeat a description of the experiments that were shown on the first occasion, although in some instances these were amplified. Mr. Mackenzie Davidson, for example, in addition to the stereoscopic x-ray transparencies and negatives, exhibited also a remarkable x-ray photograph of a bullet fired from a revolver. The photograph showed the nozzle of a revolver and the track of the bullet in its flight when fired from it. The picture is the result of an exposure not exceeding $\frac{1}{1000}$th part of a second in duration. Professor Ramsay still chose krypton as a pretty subject for exhibit. This time he produced a beautiful miniature aurora borealis. The spectrum of the aurora has been shown to contain lines due to the presence of krypton and the great majority of the lines are coincident with those of the krypton spark spectrum. The discharge can be deflected by a magnet sending out streamers in the lines of magnetic force and thus resembling the phenomena of the aurora. His colleague in research, Dr. Morris W. Travers, exhibited a compact apparatus for liquefying hydrogen. Temperatures comparatively near the absolute zero are attained by its means. The West Indian Volcanoes Committee of the Royal Society exhibited some interesting specimens of photographs illustrating the fall of volcanic dust at Barbados on May 7th and 8th, 1902, and Mr. Henry Crookes exhibited similar specimens. It is estimated that from 2,000,000 to 3,000,000 tons of this dust fell in seven or eight hours. The dust consists chiefly of the silicates of iron, lime, aluminium, and magnesium. Mr. E. J. Bles showed some living tadpoles of the Cape clawed frog which are of considerable interest from the fact that their remarkable transparency allows the course of the nerves, blood-vessels, muscles, and so on. of the head to be easily studied in the living animal. Close by was a series of specimens illustrating the life-history of the organism which is the cause of the tsetse-fly disease, shown by Mr. H. G. Plimmer; and the same gentleman, with Colonel Bruce, exhibited a specimen of apiosoma bigeminum, the parasite found in the blood of cattle stricken with Texas fever.

The demonstrations given by means of the electric lantern in the meeting room attracted considerable interest, the series of slides illustrating M. Santos Dumont's trip in his balloon and the accident to it at Monte Carlo, perhaps, claiming the closest attention. The slides were prepared from negatives taken by Mr. Buchanan in the steam launch belonging to the Prince of Monaco which was always under steam when M. Dumont made his flying excursions over the Bay of Monaco. This boat was instrumental in rescuing the aeronaut and in recovering and landing the material of the balloon after the accident. The collapse of the balloon was not complete until the shore had been reached and it was towed through the air the whole way.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 76 of the largest English towns 8555 births and 4271 deaths were registered during the week ending June 14th. The annual rate of mortality in these towns, which had been 16·7, 16·5, and 16·0 per 1000 in the three preceding weeks, further declined last week to 15·0 per 1000. In London the death-rate was 14·1 per 1000, while it averaged 15·4 in the 75 other large towns. The lowest death-rates in these towns were 6·6 in Coventry, 8·1 in Grimsby, 8·2 in Smethwick, 8·3 in Hornsey, 9·0 in Willesden, 10·2 in Wallasey, and 10·3 in Walthamstow; the highest rates were 20·3 in Salford, 20·8 in Gateshead, 21·4 in West Bromwich, 21·7 in South Shields, 22·0 in Tynemouth, 23·5 in Middlesbrough, and 25·4 in Wigan. The 4271 deaths in these towns last week included 496 which were referred to the principal zymotic diseases, against 531, 505, and 555 in the three preceding weeks; of these 496 deaths 127 resulted from measles, 115 from whooping-cough, 63 from diphtheria, 61 from diarrhœa, 55 from scarlet fever, 45 from small-pox, and 30 from "fever" (principally enteric). No death from any of these diseases was registered last week in Walthamstow, Hastings, Devonport, Burton-on-Trent, Wolverhampton, or Merthyr Tydfil; while the highest zymotic death-rates were recorded in Tottenham, East Ham, Wigan, Burnley, Barrow-in-Furness, South Shields, and Rhondda. The greatest proportional mortality from measles occurred in Derby, Oldham, Barrow-in-Furness, and Rhondda; from scarlet fever in Birmingham, West Bromwich, Bolton, and Burnley; from diphtheria in East Ham, Hanley, and Stockport; from whooping-cough in Norwich, Birkenhead, Wigan, Barrow-in-Furness, and South Shields; from "fever" in East Ham; and from diarrhœa in Burnley and Swansea. Of the fatal cases of small-pox registered last week, 29 belonged to London, nine to Tottenham, two to West Ham, and one each to Hornsey, East Ham, Leyton, Birmingham, and Swansea. The Metropolitan Asylums hospitals contained 1035 small-pox patients at the end of last week, against numbers decreasing from 1515 to 1162 at the end of the seven preceding weeks; 157 new cases were admitted during the week, against 307, 251, and 188 in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital, which had been 2236, 2266, and 2314 on the three preceding Saturdays, had further risen to 2347 on Saturday, June 14th; 282 new cases were admitted during the week, against 280, 319, and 310 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 237, 261, and 200 in the three preceding weeks, further declined last week to 167, and were 30 below the corrected average. The causes of 65, or 1·5 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Nottingham, Manchester, Salford, Leeds, Newcastle, and in 47 other smaller towns; the largest proportions of uncertified deaths were registered in Ipswich, Liverpool, St. Helens, Blackburn, Preston, Halifax, South Shields, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20·3, 19·3, and 19·3 per 1000 in the three preceding weeks, further declined to 19·0 per 1000 during the week ending June 14th, but showed an excess of 4·0 per 1000 over the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 13·9 in Leith and 14·1 in Perth to 20·3 in Glasgow and 20·5 in Dundee. The 614 deaths in these towns included 21 which were referred to whooping-cough, 18 to measles, 18 to diarrhœa, four to scarlet fever, four to "fever," and three to diphtheria. In all 68 deaths resulted from these principal zymotic diseases last week, against 55, 57, and 61 in the three preceding weeks. These 68 deaths were equal to an annual rate of 2·1 per 1000, which was 0·4 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 22 and 15 in the two preceding weeks, rose again last week to 21, of which 13 occurred in Glasgow, four in Edinburgh, two in Dundee, and two in Paisley. The deaths from measles, which had been 13 and 22 in the two preceding weeks, declined again to 18 last week, and included 10 in Glasgow and three in Edinburgh. The fatal cases of diarrhœa, which had been 14, 15, and 16 in the three preceding weeks, further increased last week to 18, of which nine were registered in Glasgow and six in Dundee. The deaths from scarlet fever, which had been six, one, and three in the three preceding weeks, rose again to four last week and included two in Glasgow. The fatal cases of "fever," which had been two in each of the two preceding weeks, increased last week to four, of which two were recorded in Glasgow. The three deaths from diphtheria corresponded with the number in the preceding week and included two in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 156, 129, and 116 in the three preceding weeks, rose again last week to 129, and exceeded by 28 the number in the corresponding period of last year. The causes of 27, or more than 4 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 22·3 and 19·8 per 1000 in the two preceding weeks, further declined to 19·7 per 1000 during the week ending June 14th. During the past four weeks the death-rate has averaged 20·2 per 1000, the rates during the same period being 15·5 in London and 19·0 in Edinburgh. The 143 deaths of persons belonging to Dublin registered during the week under notice showed a slight decline from the number in the preceding week and included 10 which were referred to the principal zymotic diseases, against eight and six in the two preceding weeks; of these, four resulted from measles, three from whooping-cough, and one each from diphtheria, from "fever," and from diarrhœa. These 10 deaths were equal to an annual rate of 1·4 per 1000, the zymotic death-rates during the same period being 1·7 in London and 1·5 in Edinburgh. The fatal cases of measles, which had been two and three in the two preceding weeks, further rose last week to four; and the deaths from whooping-cough increased to three, having been one in each of the two preceding weeks. The 143 deaths in Dublin last week included 28 of children under one year of age and 32 of persons aged upwards of 60 years; the deaths of infants showed a decline, while those of elderly persons were considerably in excess of the number recorded in the preceding week. Six inquest cases and nine deaths from violence were registered; and 53, or more than a third, of the deaths occurred in public institutions. The causes of nine, or more than 6 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE undermentioned qualified candidates for the Naval Medical Service have been appointed Surgeons in His Majesty's Fleet:—Charles Arthur Gayer Phipps, William Rhodes Harrison, Charles Kendal Bushe, Reginald Lewis Jones, Walter Goldsworthy Edwards, Frank Elliott Bolton, Robert Humphries Atkins, Stanley Samuel Howard Shannon, James Arthur Thompson, Vaughan Bateson, and Charles Joseph O'Connell.

The following appointments are notified:—Deputy Inspector-General R. Bentham to Plymouth Hospital. Fleet Surgeon W. M. Lory to the *Vernon* for the *Devastation*. Staff Surgeons: F. W. Parker to the *Wildfire* for the *Immortalité*; G. Howlett to the *Excellent* for the *Hero*; H. R. Osborne to the *Cambridge* for the *Conqueror*; H. J. Hadden to the *Excellent* for the *Narcissus*; and B. C. E. F. Gunn to the *Wildfire* for the *Edinburgh*. Surgeons: C. R. Steward to the *Australia* for the *Spanker*; G. Taylor to the *Pembroke* for the *Sheldrake*; A. Woollcombe to the *Vivid* for the *Sharpshooter*; W. P. Walker to the *Melampus* for the *Skipjack*; W. E. Ruttledge to the *Anson* for the *Speedwell*; E. F. Ellis to the *Duke of Wellington* for the *Seagull*; A. S. G. Bell to the *Pomone*, additional and on recommissioning; D. V. Lowndes to the *Hannibal*; and T. Marles-Thomas to the *Australia*.

ROYAL ARMY MEDICAL CORPS.

Colonel John Maturin is placed on retired pay. Dated June 16th, 1902.

The undermentioned Lieutenant-Colonels to be Colonels on augmentation (dated April 1st, 1902):—Blennerhassett M. Blennerhassett, C.M.G., and William B. Slaughter.

Lieutenant-Colonel S. Townsend is transferred to the charge of the Station Hospital at Secunderabad. Lieutenant-Colonel P. M. Ellis acts as Principal Medical Officer, Eastern District, *pro. tem.*

IMPERIAL YEOMANRY.

Surgeon-Lieutenant W. W. Nuttall, Leicestershire (Prince Albert's Own), resigns his commission and receives a new commission, subject to the provisions of the Militia and Yeomanry Act, 1901, retaining his present rank and seniority.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant-Colonel J. J. Saville, having resigned his Volunteer appointment, ceases to belong to the Army Medical Reserve of Officers.

ROYAL ARMY MEDICAL CORPS (MILITIA).

The undermentioned to be Lieutenants: Charles Roger Tichborne, Richard Le Geyt Worsley, and James Collins Furness.

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Devonshire: Surgeon-Captain J. W. Hodgson to be Surgeon-Major.

VOLUNTEER INFANTRY BRIGADE BEARER COMPANIES.

Gloucester and Somerset: Surgeon-Captain A. W. Dalby, from 3rd Volunteer Battalion (Somersetshire Light Infantry), to be Surgeon-Captain, and to command under paragraph 55A Volunteer Regulations. Harwich: Surgeon-Captain S. S. Hoyland, from the 1st Volunteer Battalion the Suffolk Regiment, to be Surgeon-Major, and to command under paragraph 55A Volunteer Regulations. Home Counties: Surgeon-Lieutenant C. J. Deyns to be Surgeon-Captain. Seaforth and Cameron: Surgeon-Captain J. Macdonald, from 1st Volunteer Battalion the Queen's Own Cameron Highlanders, to be Surgeon-Captain, and to command under paragraph 55A Volunteer Regulations.

NOTES FROM SOUTH AFRICA.

Lieutenant C. E. Fleming, R.A.M.C., and Civil Surgeon Symes are on passage home from South Africa.

Civil Surgeons Acland and Townsend have been discharged from hospital to duty.

MENTIONED IN DESPATCHES.

A despatch dated March 1st from Lord Roberts in continuation of a despatch dated Sept. 4th, 1901, is published in the *London Gazette* of June 17th and contains, among others, the following names. The "mentions" bear date Nov. 29th, 1900.—

Lieutenant-Colonel R. V. Kelly, New South Wales Army Medical Corps; Surgeon Lieutenant-Colonel E. Fiset, Medical Officer Royal Canadian Regiment; Surgeon-Major F. J. Ingolby, West Australian Medical Staff; Captain D. D. Shanahan, R.A.M.C.; Quartermaster and Honorary Lieutenant A. Freshwater, R.A.M.C. (*since deceased*); Quartermaster and Honorary Lieutenant H. S. Brook, R.A.M.C., and Quartermaster and Honorary Lieutenant G. F. Short, R.A.M.C.

Civil: Lady Henry Bentinck, Portland Hospital; Lady Furley, Red Cross Depôt, Cape Town; Mr. G. Bonham-Carter, Assistant Commissioner, Red Cross Society; Mr. Donald James Mackintosh, Scottish Red Cross Society; Mr. J. G. Hamilton, Imperial Yeomanry Hospital; Dr. J. Purves Stewart, civil surgeon, Imperial Yeomanry Hospital; Mr. H. Tener Galbraith, civil surgeon, Dundee, Natal; Mrs. Theodosia Bagot, Portland Hospital; Mrs. P. H. Johnston, president, Army Hospital Aid Society, Natal; Mrs. Redpath, colonial nurse, Buluwayo, Mrs. Melina Rorke, colonial nurse, Buluwayo; Miss Frances Amelia Lowrie, matron, Bourke Hospital, Pretoria, and Miss Ada Whiteman, matron, College Hospital, Maritzburg, and Leper Hospital, near Pretoria.

Scottish National Hospital: Surgeon-Captain R. Stirling, 4th Volunteer Battalion the Black Watch (Royal Highlanders); Dr. J. M. Cowan, civil surgeon; Dr. J. Aitken, civil surgeon, nursing sister Miss Margaret Butler Alexander, Queen Alexandra's Imperial Military Nursing Service Reserve; Nursing Sister Miss Annie Henderson, Queen Alexandra's Imperial Military Nursing Service Reserve; and Nursing Sister Miss Mary Ann Forbes, Queen Alexandra's Imperial Military Nursing Service Reserve.

Hospital Ship *Maine*: Major J. Meek, R.A.M.C., G. E. Dodge, civil surgeon; Mr. T. W. Hastings, civil surgeon; Mrs. George Cornwallis-West, Miss Eleanor Charlotte Warrender; Staff-sergeant (now Sergeant-Major) S. J. How, R.A.M.C.; Mr. J. J. Reilly, male nurse; and Mr. W. B. Ruth, male nurse.

Hospital Ship *Princess of Wales:* Major A. H. Morgan, D.S.O., A.M.S. (retired); Captain A. Pearse, R.A.M.C.; Superintendent Miss Clara Mavesyn Chadwick, Queen Alexandra's Imperial Military Nursing Service; Nursing Sister Miss Helen Hogarth, Queen Alexandra's Imperial Military Nursing Service Reserve; Staff-Sergeant W. Higgins, R.A.M.C.; and Lance-Sergeant J. Brown, R.A.M.C.

In a despatch from Lord Kitchener, dated Pretoria, April 8th, 1902, the name of Lieutenant-Colonel J. D. Edge, R.A.M.C., is mentioned.

THE LATE WAR IN SOUTH AFRICA.

Peace has come and has been practically sealed and ratified by the gathering together and the laying down of arms on the part of the various Boer forces lately opposed to us in the field. The news of the surrender of some 17,000 of our late enemy, and still more perhaps of the promising conditions under which this has taken place, has been everywhere received as glad tidings of great joy. If in the past history of the world the saying was ever true that the unexpected is that which happens it has been emphatically so in the case of the late war. Turn which way we will we are met with facts at variance with almost all that was confidently expected or predicted as at any rate most probable. It is impossible even for the most thoughtless to avoid all reflection on the events that have occurred within the past three years. To begin with, the British Government did not expect war and the Kruger ultimatum making it inevitable found this country unprepared for war, whereas the Boers were prepared; and now that peace has come all that was prognosticated about what would be the spirit and conduct of our late enemy has turned out to be as ill-founded as it could well be. The Boers manifest no signs of that depression and humiliation which are supposed to characterise a defeated army. Looking back, as they may well do with great pride, to the part they have played throughout the campaign they now apparently recognise and accept the inevitable and manfully as well as loyally take their place among the subjects of King Edward VII. There are no signs of that bitter and inextinguishable hate and racial animosity which were prophesied would be the case; and the Boer officers and soldiers have been everywhere received with every mark of sympathetic respect, good feeling, and comradeship by the soldiers of the British army. Every Tommy Atkins is now a strong pro-Boer. The war has taught us lessons that were sorely needed, it has been the graveyard of several military reputations, it has revolutionised many of our ideas and military systems, it has enlarged our views and experience of army medical administration, surgery, and medicine, and it has led to a scheme of reform in our army and naval medical services the full effects of which have yet to appear. That our army system generally will be tried and reformed by the results of the experience gained in the late war can scarcely be doubted.

SOUTH AFRICAN CASUALTIES.

We desire to direct the attention of those of our readers who have not yet seen it to an interesting article from "An Actuarial Correspondent" in the *Times* of June 16th on this subject. The article should be referred to and read *in extenso* by those interested in the casualty statistics of the late war. Tables are given of the death-rates per 1000 among officers who have been killed or died from wounds and from disease respectively during the first, second, and third years of the war, and for non-commissioned officers and men for the same years, also calculated at rates of 1000 per annum, of those killed or died from wounds and deaths from disease. From these tables it would appear that, while the men have suffered much less in battle than the officers they have been more subject to disease. The disease-rates of both officers and men are, however, stated to be remarkably low, especially when it is remembered that the ordinary rate of mortality of British troops on foreign service is 15 per 1000 per annum. Comparing one period with another the improvement during the last eight months in South Africa was, moreover, most marked, few more officers and men having, it is stated, died from disease than would have died if no war had been going on. With the exception of the first year's fighting, when the losses both from battle and from disease were very heavy, the casualties in the late war compare favourably with those of most recent campaigns—the Franco-Prussian and American civil wars for example.

BOER AND BRITISH.

Amid the many manifestations of the present mutual good feeling existing between the late belligerents in South Africa which have shown themselves since peace has been declared we may call attention to one of a pathetic nature that occurred recently at Standerton. A Boer officer of the Standerton Commando named Swarts who had died from enteric fever was buried with military honours. The coffin was covered with the Union Jack and carried to the graveside on a gun-carriage. Colonel Batson, the commandant, all the officers of the garrison, and all the garrison followed the *cortège.* General Britz also attended.

DEATHS IN THE SERVICES.

Inspector-General of Hospitals and Fleets William Henry Sloggett, R.N. (retired), at Paignton, Devonshire, on June 10th, in his eighty-second year. He entered the Royal Navy in 1842 and retired with the rank of inspector-general in 1875. The funeral, which took place on June 13th at Paignton, was very largely attended. The deceased gentleman since his retirement had resided at Paignton, where he was highly esteemed.

THE ROYAL ARMY MEDICAL CORPS AND THE CORONATION.

Six officers and 200 non-commissioned officers and men of the Royal Army Medical Corps with 24 horses will take part in the Coronation procession of June 26th and 27th.

It will be seen by a reference to our Parliamentary Intelligence that as there are instances on record of the award of medals to the masters of transport and hospital ships, the War Office is considering whether these precedents should be followed, and, if so, to what extent in the case of masters, officers, and crews of transport and hospital ships employed during the war in South Africa.

Correspondence.

"Audi alteram partem."

THE RELATION OF MENTAL SYMPTOMS TO BODILY DISEASE.

To the Editors of THE LANCET.

SIRS,—There is much in Dr. Nathan Raw's excellent article on "The Relation of Mental Symptoms to Bodily Disease"[1] which provokes comment—mostly laudatory, sometimes critical; but from comment of either kind I could have refrained, had he not in his closing paragraphs violently assaulted one of my most cherished fads. He says of persons suffering from delirium tremens that they are "the most dangerous lunatics for the time and yet they cannot be certified as legally insane." If the Lunacy Act, 1890, were so drawn that the most dangerous lunatics could not be legally certified as insane, it would be a greater legislative failure than even the last Workmen's Compensation Act. But I venture to assert without the slightest hesitation that it is not so drawn. The certifier must state that the patient is a lunatic, an idiot, or a person of unsound mind, and a proper person to be taken charge of and detained under care and treatment. The words of the Act make no reference to the cause of the malady or to its probable duration, and whether the insanity is due to excessive drinking or to other cause, whether it is likely to be temporary or permanent, are not matters which the certifier need take into consideration in order to satisfy the law. They may or may not make a great difference as to the wisdom and policy of certifying the patient, but to the legality of the certificate, if the symptoms are sufficient to warrant the certificate being made, they make no difference whatever. For my own part I should have no hesitation in certifying a patient with delirium tremens if he were sufficiently insane to be certified, and such patients are admitted into lunatic asylums every week without the legality of their certifications being questioned. In one case in which the legality was questioned, the judge explicitly ruled that the causation of the insanity had nothing to do with the matter—that if a man was insane from drink he was as rightly certifiable as if he were insane from any other cause.

Dr. Raw is exercised as to whether it is necessary for a man "to bear the stigma of having been certified as a lunatic when he was simply suffering from temporary mental aberration the result of bodily disease. There can be no question whatever that an asylum of some sort is the best place for the patient, but he need not be certified as insane, at any rate until it is seen whether the insanity is likely to be permanent or not.' Dr Raw is not alive to the practical difficulties of dealing with insane persons without certification. The law which would render an insane person liable to be sent to, and detained in, an asylum, deprived of the control of his person and of the management of his property without certification, would lay the same liability upon a sane person, and without certification every safeguard of the sacred liberty of the subject would be utterly swept away I am unable to appreciate the distinction drawn by Dr. Raw between insanity on the one hand and "temporary mental aberration the result of bodily disease" on the other It is but rarely that we can be quite sure that mental aberration will be of short duration, and even if we could usually do so, and even if we could agree upon the precise duration which is to be termed temporary, there remains the fact, or what I believe to be the fact, that, whether "temporary' or permanent, every manifestation of insanity is the result of bodily disease. With Dr. Raw's conviction that a large number of people are certified as lunatics who are simply suffering from insanity the result of, or associated with, some form of bodily disorder or of poisoning I should be in complete accordance, but when he contends that such persons are not really insane I should join issue with him, for I should contend that the "large number' includes every insane person who is certified as such. In short, I deny altogether the existence of Dr Raw's distinction between mental aberration and insanity All that I recognise is a difference in degree. Every case of mental aberration or insanity is, in my view, the result of, or associated with some form of bodily disorder or of poisoning, and I protest with all the vehemence of which I am capable against the view that insanity is a thing apart, a specific entity, having no community of nature with trifling and temporary "aberrations of mind.' This view is a lingering remnant of the belief in the demoniacal possession of the insane and is the most serious obstacle to the right understanding of insanity That it should be held by a man of Dr Raw's ability and eminence goes far to excuse the otherwise unpardonable length of this communication.

---

I am Sirs, yours faithfully,

Catford S.E. June 16th 1902. CHARLES MERCIER.

OBSERVATIONS ON DIET

To the Editors of THE LANCET

SIRS,—Probably Dr Harry Campbell's shoulders are sufficiently broad to withstand the onslaught which Dr F W Forbes Ross has thought proper to direct against him in THE LANCET of June 14th 1902, p. 1724 on the subject of his "highly theoretic and erudite contribution" with reference to the feeding of old people. Nevertheless, as one whose practical experience bears out and confirms Dr Campbell's views I may be permitted to enter the lists and shiver a lance in the cause of ' physiological feeding for the aged"—an expression which, I gather from Dr Ross's letter, is the same thing as the metabolism of starvation.

I find myself in complete accord with Dr Ross's observation that ' it is quite time we as a profession began to revise our practice and preconceived notions in certain directions where diet is concerned" as also with his clinical experiences, but I take exception to the deductions and generalisations which he draws from the latter It is in the highest degree improbable that a man living on "the fat of the land or even on a "generous, good full diet" (*vide* Dr Ross's dietetic canons) with lung kidney and heart perhaps as the sequelæ of this mass stimulation would derive any immediate benefit from an ill-considered restriction of diet indeed, deprived of the mass stimuli to which his metabolism (*pace* Dr Ross) has been educated and accustomed I should expect the rapid dissolution which Dr Ross so pathetically deplores But what is this, after all other than the phenomena which appear in the alcoholic or morphomaniac when his particular variety of poison stimulus is reduced to a physiological and pharmacopœial dose! I imagine it would not be seriously contended that a full generous exhibition of either alcohol or morphia would be productive of longevity because when deprived of them suddenly their victims ' sink rapidly to dissolution." *Mutatis mutandis*, the argument is, I trust, a sufficient reply to Dr Ross's *verb sap* I am, Sirs yours faithfully,

London June 13th 1902. ERIC PRITCHARD

To the Editors of THE LANCET

SIRS,—I have had very considerable experience in dieting the aged during the last 20 years My experience gained is quite the opposite from Dr F W Forbes Ross's views, expressed in THE LANCET of June 14th, and is more in accord with those of Dr Harry Campbell if I read correctly what he intends to convey to the reader by the term "spare diet. The aged do not require quantity but quality in their foodstuffs and a full diet is generally harmful to the majority of aged patients. I always prescribe a diet rich in nutrient substance easy of digestion and assimilation, but spare in quantity The organs of aged people are more or less worn out, and this refers more particularly to the digestive organs so that if you tax them with foods which require much digestion and contain a large quantity of waste material fermentation is sure to set in—the very bugbear of old age—which produces most dangerous and unpleasant symptoms.

How many aged gentlemen who dine well but not wisely at their clubs have gone home and died suddenly after a full meal and how many suffer from most painful gouty affections from living on a full diet. Of course, there are many exceptions My old friend Dr Pickett's father who died at the age of 95 years, always used to eat a hearty meal of bread cheese, and ale before going to bed. My great-grandmother, who lived to 93 years of age, had three full meals a day We are generally called to diet the feeble and weak, who, I am afraid form the majority, not the minority, of the aged The less chance of auto-toxin there is by there being little waste material in the diet the greater will be the success of our treatment. I am, Sirs, yours faithfully,

THOMAS DUTTON

Manchester-square W June 14th, 1902.

SORE-THROAT AS A PREMONITORY SYMPTOM OF ACUTE RHEUMATISM

To the Editors of THE LANCET

SIRS,—The association of sore-throat with rheumatism is well known to the profession, but I desire to draw attention to a certain condition of the throat which in not a few cases signals the onset of the graver malady

I have had under my care two cases which serve the purpose of illustrating my meaning 1. I was called to attend a married man, aged 34 years, who complained of sore-throat and a marked feeling of general illness. On examination I found the throat red and relaxed but altogether clear of any ulceration or deposit—what might be quite properly and fully described as a catarrhal throat, no swelling of glands or pain about the neck and only little difficulty in swallowing, temperature slightly raised, barely 100° F, a deposit of lithates in the urine which was otherwise normal but no pain or discomfort whatever about the body or limbs. So far the case appeared simple enough with this exception—the man seemed to be ill out of all proportion to anything I could discover The usual treatment was adopted and at the end of five days the patient was to all intents and purposes restored to his usual health and extremely anxious to return to work. I advised him strongly to the contrary, in fact, to remain at home another week as I was not certain of his complete recovery However he persisted and went, with the result that in four days time he was back in bed with a sharp attack of rheumatic fever 2. This case was very much on all fours with the one described except that the patient's throat was slightly worse and that at the end of 10 days he complained of a fixed pain in one heel which was undoubtedly rheumatic. He decided to follow the course I suggested however and remained at home making a good recovery and resuming work at the end of three weeks well and strong and none the worse for his attack.

These two cases which I have described and some few others of a like nature which have come under my notice show at least the possibility of rheumatic fever supervening the condition of the throat being its initial manifestation. The fact that there is no pain or swelling of joints at the onset should not mislead us, for in neither of the cases cited did the patients suffer any pain whatever for the first few days; indeed, one actually went to work, the subsequent pain not yet in evidence. All such cases as I have described should be viewed with suspicion, the patient carefully watched and ordered rest and warmth for at least one week, and a further period of seven days in the house with appropriate medicinal treatment, until he is *quite* restored to health and we have no cause for further anxiety. In this way I am sure we might often ward off an attack of acute rheumatism with much subsequent advantage to our patients if with little credit to ourselves.

I am, Sirs, yours faithfully,
D. F. WHITELEY.

Fulham, S.W.

VARICOSE VEINS.

To the Editors of THE LANCET.

SIRS,—I read with interest Mr. Pearce Gould's lecture on Varicose Veins in THE LANCET of March 1st, p. 576, and your comment thereupon in your issue of March 22nd, p. 833, and I expected some critical correspondence to follow. As there has been none as yet perhaps you will admit a few unavoidably belated observations from me.

Mr. Gould says that "two views of the nature of varicose veins are commonly held to-day. One regards them as the result of the yielding of the veins to an increased intravenous pressure due to an obstruction to the flow of blood up to and through the heart. ...... According to the other view, varicose veins are to be regarded rather as venous outgrowths, a superabundant development of venous tissue—venous angeioma." He rejects the former and adopts the latter. But I would venture to suggest that another factor exists which he has overlooked, one so obvious that I have always thought it sufficient, though often combined with pressure, to account for the existence of varicose veins in nearly every case. I mean relaxation of the muscular coats of the veins and hence diminished resistance. Normally the veins are kept duly contracted by the tone of the muscular fibres that the walls possess. But under certain conditions of debility, and in some individuals much more than in others, these fibres become relaxed and the vessels dilated and weak. The chief of these predisposing conditions is temperature; trouble and distress from varicose veins is mainly a seasonal affection, occurring in hot weather. Just as attacks of certain diseases occur punctually and periodically in some patients at certain seasons year after year, so have I been accustomed to find suffering from distended varicose veins on the advent of the hot weather of summer. If one only looks at the back of one's own hand from time to time the conspicuous difference in the size of the veins according to the external temperature will be conspicuous; the veins may be small and almost invisible on a cold day, but large, full, and distended on a hot one. And this applies to all the superficial veins of the body; the deeper ones are better protected and supported. Thus the pressure of blood from gravitation in the lower limbs increases the distension, causing in time permanent dilatation and incompetence of the valves, and then the morbid structural changes of varix result. Is not this a true and sufficient cause? Heat and cold have this effect more or less on the muscular tissue of all superficial blood-vessels, arteries as well as veins. When the wind was in the east Mr. Jarndyce (if I recollect "Bleak House" aright) used to retire to his growlery, owing to the mental depression and irritability due to increased arterial tension brought about by exposure to cold. Some persons are made for warmth, others require a cool atmosphere. Varix is almost always aggravated in the summer. In that season of 1898 in London I saw a woman with extreme varicosity of the veins of both legs who was also advanced in pregnancy. One day a vein burst in each leg simultaneously. Pregnancy certainly has a considerable effect in inducing or increasing the condition. Ovarian and uterine tumours are less potent because their growth is so much slower. Thus I maintain that over-distension of a certain set of relaxed veins by a column of blood is the chief cause; obstruction is a secondary one. Symptoms of pure obstruction are absent because venous circulation is still carried on, especially through the deep veins. Mr. Gould, like others, has met with the disease much more frequently in men than in women, probably because men's occupations compel them to stand about more than women, and on this account men are more liable to become incapacitated and seek relief.

If the angeioma theory favoured by Mr. Gould were the correct one, why is it that varicose veins are always met with in the dependent parts of the body? Why, for instance, do they never occur in the neck or arms? The presence of adventitious muscular tissue in the varicose dilatations is no doubt due to a process of compensatory hypertrophy. The reappearance of veins near the scar after excision of a portion of a vein is doubtless due to the enlargement and growth of small pre-existent veins to take the place of that which has been removed, just as arterial branches enlarge after ligature of a trunk. Therefore the advantages of a surgical operation may be only temporary. The reason why varix does not ensue upon ordinary venous obstruction from cardiac disease is, I believe, that the veins have not become relaxed and thus the pressure falls upon the terminal veins and capillaries, causing œdema.

I am not aware that I am putting forward anything particularly novel in offering the above remarks—in fact I believe that the ideas are old-fashioned and common. They seem, however, to present a satisfactory and intelligible explanation of the condition and thus there seems no need to fly to a more mysterious theory. Mr. Gould will, I know, welcome any honest criticism.

I am, Sirs, yours faithfully,
F. LUCAS BENHAM, M.D., M.R.C.P. Lond.

Exeter, South Australia, May 9th, 1902.

NUTMEG POISONING.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of April 12th, p. 1034, Mr. R. A. Pitter relates a case of nutmeg poisoning and asks for information as to other cases. Some years ago I was called to see a woman who had taken the whole of a ground nutmeg mixed with gin. The symptoms were exactly the same as those described by Mr. Pitter and the woman nearly died. The dose was taken to procure abortion; whether it had that effect I did not learn. The friends volunteered the remark that the woman had taken the nutmeg in spite of the fact that a neighbour had nearly died from the same cause shortly before. At the time I asked a good many friends, medical and lay, if they knew anything of the poisonous properties of nutmeg in large doses. None of them did except one old lady from the north of England, who stated that she and people in her part knew them well. Squire states that nutmeg in large doses is a narcotic poison.

I am, Sirs, yours faithfully,
Geelong, Victoria, May 13th, 1902. S. MABERLY SMITH.

CHLOROFORM FATALITIES.

To the Editors of THE LANCET.

SIRS,—It seems to me that M. Huchard's statement—as reported by your Paris Correspondent (*vide* THE LANCET, June 7th, p. 1649)—that among 100 deaths under chloroform not more than 10 are concomitant with organic heart disease, ought not to be allowed to pass unchallenged. The St. Bartholomew's Hospital statistical records for the 26 years 1875–1900 contain references to 31 fatalities of this kind, of which some particulars are given as to 30. In 26 of these cases death appeared to have resulted from cardiac failure and from respiratory failure in four. Of the former group of cases it is stated that the heart *presented signs* of extensive organic disease in nine instances (hypertrophy and dilatation, often with valvular disease, in six, fatty degeneration in three). In only six instances was the heart found to be normal. In 12 cases the condition of the heart is not stated (no post-mortem examination). Thus of 15 cases in which the condition of the heart was actually noted post mortem, in nine this organ was extensively diseased. Hence it may be concluded that morbus cordis adds greatly to the risks of chloroformisation. In five of the foregoing cases the cardiac disease was complicated by extensive pulmonary disease and nine of the patients were in an exceedingly debilitated condition. Most of these fatalities occur during the early stage of chloroformisation while anæsthesia is incomplete (in 11 cases before the operation had been commenced).

I am, Sirs, yours faithfully,
Clifton, Bristol, June 17th, 1902. W. ROGER WILLIAMS.

THE ANNUAL TEMPERANCE BREAKFAST AND THE BRITISH MEDICAL ASSOCIATION

To the Editors of THE LANCET

SIRS,—I shall feel obliged by your kindly allowing me to announce through your columns that the annual breakfast to those members of the British Medical Association who will kindly apply for cards will be given by the National Temperance League on Thursday morning of conference week as usual. I am, Sirs, yours faithfully,

J T RAE, Secretary

Paternoster House, London E C June 17th, 1902.

TEMPORARY REMINISCENCE OF A LONG-FORGOTTEN LANGUAGE DURING THE DELIRIUM OF BRONCHO-PNEUMONIA.

To the Editors of THE LANCET

SIRS,—With reference to Dr C. A. Mercier's remarks on Dr H. Freeborn's case of temporary reminiscence of a long forgotten language during the delirium of broncho-pneumonia in THE LANCET of June 14th, p. 1685 I should like to say that personally I do not believe in Coleridge's tale of the illiterate maid servant who talked Greek and Hebrew in her delirium. Indeed, I thought that the tale was known to have been a fabrication. Dr Leonard Hill in his "Manual of Physiology," p. 379 states that the whole story was a mischievous invention of Coleridge's.—I am, Sirs, yours faithfully,

GEORGE PERNET

Upper Gloucester-place, N W , June 28th 1902

WHAT IS SCROFULA?

To the Editors of THE LANCET

SIRS,—Owing to pressure of work I have been unable to reply before this to the letter of Dr J Tatham in THE LANCET of May 31st, p. 1560 I am afraid that I can hardly regard his arguments on the retention of the word "scrofula" as convincing. In reply he quotes a paragraph from a System of Medicine which in substance says that "scrofula" may or may not be due to the tubercle bacillus. This is certainly very informing , but against his quotation I may draw attention to the following, taken from the latest edition of Quain's Dictionary "Scrofula (*scrofa*, a sow), a term applied to a supposed hereditary tendency to slowly progressive chronic inflammations and caseation, especially of lymphatic glands. The large majority of such cases are now known to be instances of chronic local tuberculosis, *and the term is rapidly falling into disuse*" The italics are mine. This, I venture to suggest, is precisely what is happening—the up-to-date teachers in the medical schools are so instructing medical students that in another generation or so the word "scrofula" will be forgotten. Again, Dr Tatham alleges as another reason for his retention of the term that "scrofula,' as a term, "as distinct from tuberculosis, is in common use by medical men, not a few of whom (including certain physicians and surgeons of eminence) still believe the conditions which these terms imply to be distinct." I cannot help thinking that it would be just as wise to argue that the word "tubercular," expressive of lesions caused by the tubercle bacillus, should be retained because certain physicians and surgeons of eminence and other similar practitioners who know more about "scrofula" than 99 per cent. of the profession use it instead of the universally adopted term "tuberculous." It is noticeable, however, that Dr Tatham has expunged the word "tubercular" from the list of diseases due to tuberculosis. Lastly, I come to the argument which is, perhaps, the most extraordinary of all Dr Tatham thinks that because "scrofula" has figured in the reports of the Registrar-General from their commencement therefore the term should still be retained "lest the comparability of figures in a series of years should be impaired"—that is to say, by affording the opportunity of filling in death certificates with the term "scrofula" he will enable a few members of the profession to satisfy their pathological consciences and thus imperil the accuracy of his reports However, even in the present state of our knowledge it does not require a prophet to forecast what the record for deaths from "scrofula" will ultimately become. Presumably in 10 years' time we shall have some enterprising journalist, on the prowl for new "copy," contributing a paper to a magazine with the comforting title of "The remarkable decline in the mortality from 'scrofula' based upon the statistics of the Registrar-General." I am, Sirs, yours faithfully,

June 17th, 1902. PES.

THE OPEN-AIR TREATMENT OF PULMONARY PHTHISIS.

To the Editors of THE LANCET

SIRS,—The following testimony to the good effect of open air and mountain air in phthisis quoted from the late Geo F Buxton's "Adventures in Mexico and the Rocky Mountains" (Murray, 1849, p. 288), may interest some of your readers —

"My two companions had left the United States the preceding year, having been recommended to try the effect of change of climate on a severe pulmonary disease under which both laboured. Indeed, they were both apparently in a rapid consumption and their medical advisers had given up any hope of seeing them restored to health. They had remained in the mountains during one of the severest winters ever known, had lived upon game, and frequently suffered the privations attendant upon a mountain life, and now were returning perfectly restored and in robust health and spirits. It is an extraordinary fact that the air of the mountains has a wonderfully restorative effect upon constitutions enfeebled by pulmonary disease, and of my own knowledge I could mention a hundred instances where persons whose cases have been pronounced by eminent practitioners as perfectly hopeless have been restored to comparatively sound health by a sojourn in the pure and bracing air of the Rocky Mountains, and are now alive to testify to the effects of the invigorating climate. The elevation above the level of the sea of the plains at the foot of the mountain is about four thousand feet, while the mountain valley of the Bayou Salado must reach an elevation of at least eight or nine thousand and Pike's Peak has been estimated to exceed twelve thousand." I am, Sirs, yours faithfully,

June 16th 1902. F L B

NOTES FROM INDIA

(FROM OUR SPECIAL CORRESPONDENT.)

The Decline of the Plague Epidemic —The All India Victoria Memorial.—Results of the Census.—A Case of Medico-Legal Interest —Legislation against Indians in Natal.

THE plague epidemic is rapidly declining throughout India. For the past week there have been 5493 deaths reported as against 7008 for the previous seven days. The Punjab, which is chiefly affected, reports 4234 deaths, being a decline of 1219.

The All India Victoria Memorial Fund has now reached the large amount of Rs. 4 500,000, equivalent to about £300,000

The census tables show a great variation in population in certain districts. While there has been an increase of over 335,000 people in Sind there has been a decline of over 650 000 in Bombay Bengal, Madras Burmah, and the Punjab make up for the 10,000 000 increase in the British provinces Aden has been practically stationary It is in the Native States that the effects of famine and immigration are most apparent. Rajputana has lost 2,250 000 of its inhabitants, the Central India Agency over 1 500 000 and the Bombay native states over 1,000,000. Baroda, Gwalior, and Hyderabad have all lost considerably An explanation is wanted for the much larger decreases in native territory

A case of considerable interest from a medico-legal point of view is reported by the chemical examiner to the Bengal Government A murder was committed at the Bengal Club in Calcutta and examination of the blood-stains on the garments of the murderer showed that the blood contained filariæ. This established a connexion between the murderer and his victim and it indicated, moreover, that the murder had been committed at night.

The proposed legislation against British Indians in Natal seems oppressive Every male will be liable to pay a tax on reaching the age of 16 years, even though he was born in the colony, and every female at the age of 13 years. This will bear very hardly upon the heads of families, because children can with difficulty pay £3 a year.

May 31st.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Ventilation of Public Buildings.

THE ventilation of our public buildings is often notoriously bad, but people are so accustomed to it that they take it as being in accordance with natural law. Manchester is probably no worse than other towns, for the proper supply of fresh air to, and the removal of foul air from, buildings of all kinds are problems not solved by our architects and engineers. If anyone wishes for an object-lesson let him go to the gallery of the Free Trade Hall when one of the Hallé concerts is half over. The city coroner thinks the Minshull-street coroner's court supplies a good illustration and it has, indeed, long been the subject of much complaint. He referred to the matter when holding an inquest last week and expressed the hope that now that a city architect was appointed he "would direct his attention to the ventilation of public buildings, a matter which had been much neglected." He thought that where juries had to sit for a long time they had a right to demand that they should have fresh air. Mr. D. Walmsley, inspector of factories, who was in court, said that "he had never experienced a worse condition of ventilation than he had done that day," and that if the court were a factory "somebody would be convicted for overcrowding." When used for public purposes public buildings are for the time being almost always overcrowded and the difficulty is to provide sufficient interchange of air in a bearable fashion to meet this abnormal state of things. The problem is difficult, but the evil is great and the remedy for it is deserving the best efforts of the most able.

Heywood and Sanitation.

At the meeting of the Heywood Town Council on June 12th several matters of interest were brought forward. The chairman referred to the annual report of the medical officer of health and drew attention to the fact that of 70 children who had died from diarrhœa 50 were "bottle-fed." The ignorance, want of correct ideas as to cleanliness, and very often the apathy and indifference, of those who have charge of the children whose mothers are many of them working in the mills are sufficient to account for much of our infant mortality. Little can be hoped for the present generation from the teaching in our elementary schools, but the kindly educational influence of ladies of tact, sympathy, and good sense, as shown by the successful working of the Manchester Ladies Health Society, may do much to bring about a reduction of the high infant death-rate and the brightening of the homes of the working class. It cannot but be thought that some of the energy and restlessness which sends young ladies to flood the ranks of the nurses might with advantage be directed to the mitigation of the conditions so fatal to the infants of our town populations. But perhaps the uniform would be missed. Heywood is also engaged in several public schemes for which the Local Government Board has sanctioned the borrowing of £28,292—£4538 for a refuse destructor and the remainder for sewerage works. The health committee has taken action with the view of putting a stop to the practice by some of the butchers of "blowing" their meat, each butcher having been served with a notice.

Coöperative Convalescent Home.

The local coöperative societies propose to establish a convalescent home for their members at Norbreck on the Lancashire coast, two miles north of Blackpool. It is to accommodate 120 persons with space for future extension and is estimated to cost at least £25,000. This movement seems to be general among the coöperative societies, for the northern section now has a home of its own at Gilsland in Cumberland, while the midland and southern sections are discussing the question of making similar provision for the benefit of their members.

Drunkenness among Women.

It is sometimes made an occasion of reproach that the clergy do not make as much use of their position and opportunities to help forward sanitary work as they might do—that they are so much engrossed with their spiritual work that they are heedless of the body which the spirit inhabits. This may sometimes be so, but the Bishop of Manchester, in a recent visitation address to the Bolton Rural Deanery, did not lay himself open to this charge. He introduced a discussion as to whether there was sufficient authority in Bolton to prevent overcrowding, as to whether they were trying to make the drains good, to abolish back-to-back houses, and to put the courts into a thoroughly sanitary condition. He drew attention to the fact, revealed by returns which he had received, that while intemperance among men was diminishing it was unhappily increasing among women. "If that should go on," he said, and quite truly, "it was the death knell of our race." He spoke strongly on the subject. "They must make an end of this hideous thing. It was a matter of life and death for them." If necessary he would make it penal to supply a woman either in a public-house or shop "with the means of brutalising herself." No surer means of lowering our position in the scale of nations both physically and morally could be devised than by increasing the temptations and fostering the taste for drink among our women of all classes, and, though the bishop did not mention it, the grocers' licences minister to both and might well be repealed.

Struggle with a Madman.

Dr. W. A. Smith of Darwen had an unpleasant experience on Sunday evening. A man went into his surgery and seized Dr. Smith by the throat, when a violent struggle occurred and fortunately the man was overpowered. The police were sent for and he was taken to the police-station and committed to the Blackburn Workhouse Infirmary for 14 days for medical examination. It was fortunate for the doctor that he was able to treat his patient successfully.

June 17th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Important Movement in Northumberland and Durham.

IN order to raise the general and financial status of the medical profession in the counties of Northumberland and Durham two associations—viz., the Northumberland and Newcastle Medical Association and the County of Durham Medical Union—were formed some time ago. The former association has now a membership of close on 200, while the latter has almost 250 members. With a view to strengthen the two associations against possible offenders it was agreed that the presidents of both should approach the consultants of the district to ascertain whether they would be prepared to refuse to meet those practitioners whom the councils should judge to be offenders against the objects of the associations. For this purpose a meeting of the consultants was held on June 11th in the library of the Royal Infirmary, Newcastle, Dr. E. Jepson, President of the County of Durham Medical Union, being in the chair. Dr. Jepson having explained the object of the meeting Dr. G. H. Hume pointed out that the councils of the associations were asking the consultants to assist in the punishment of these offenders without the consultants having any voice in the judgment of the cases against them. That, Dr. Hume said, was a position which the consultants would not accept, but he thought that if a small committee were appointed, on which the consultants had proper representation, to inquire into and to adjudicate on all such cases a solution of the difficulty might be arrived at. After some discussion, during which several consultants spoke in eulogistic terms of the proposal, it was finally agreed, subject to the approval of the two associations, and on the motion of Dr. Hume, seconded by Mr. J. Rutherford Morison :—

> That a committee be formed to investigate and decide upon cases of alleged unprofessional conduct which shall be referred to such committee by the council of either association.

Mr. Rutherford Morison then proposed and Dr. A. M. Martin seconded :—

> That the committee for the investigation of cases of alleged unprofessional conduct shall consist of the presidents of the two associations, two consultants (to be appointed by the consultants of the district), and two members from each of the associations.

These two motions were passed unanimously and have since been adopted by the joint council of the two associations. Dr. J. H. Hunter of South Shields and Dr. R. S.

Hubbersty of Sunderland were nominated as the representatives of the County of Durham Medical Union; Dr. W. L. Ruxton of Newcastle and Dr. W. S. Campbell of Whitley, Northumberland, were nominated as the representatives of the Northumberland and Newcastle Medical Association; the consultants have not yet nominated their representatives. On account of the formation of this "judicial committee" the councils of the two associations will in future act as grand juries to select the more serious cases for investigation and judgment by the "judicial committee"

June 17th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Cardiff Infirmary.

ONE of the rules regulating the admission of in-patients to the Cardiff Infirmary provides that such persons only shall be admitted as are unable to pay for medical attendance and support during their illness, though cases of accident or emergency may be admitted without any regard to the circumstances of the patient. As there appears to have been some abuse of this rule the secretary of the infirmary has sent a circular letter to the medical practitioners of Cardiff pointing out that there are in the town several private hospitals in which patients who ought not to be admitted to a charitable institution can be treated. With regard to the treatment of out-patients a rule of the institution establishes a wage-limit for applicants of 18*s.* per week for single men or women, 23*s.* per week for a man and wife, and 2*s.* per week for each child. Any person found upon investigation to be earning more than these sums may be refused attention or may be referred to the provident dispensary

Small-pox.

The outbreak of small-pox at Swansea shows signs of declining. Until June 14th, when two patients were removed to the hospital, there had been no case reported for nearly a fortnight. Since the beginning of the epidemic in December there have been 71 cases and 14 deaths have occurred. One case at Chester and two at Ystalyfera have been traced to infection in Swansea. In a recent report the medical officer of health (Mr. Ebenezer Davies) states that no death had occurred at the small-pox hospital after successful revaccination. During the month of May 135 contacts were kept under observation and 85 were revaccinated.—A man was fined £10 on June 12th at the Swansea police-court for obstructing the execution of a magistrate's order requiring his child, who was suffering from small-pox, to be removed to the small-pox hospital. The facts of the case have already been alluded to in THE LANCET[1] It was contended by the defendant that the children, for there were two who were ill, were perfectly isolated and could not be a danger to other persons in the house notwithstanding the fact that there were subsequently attacked with the disease the maid-servant, the children's mother, their aunt, and a child living next door.—A Greek sailor was removed to the Barry Small-pox Hospital on June 14th from a ship which had arrived from Sligo three days previously.—The two small-pox patients have been discharged from the Aberdare Hospital and the town is now free from the disease.

The Workmen's Compensation Act.

An important decision was given in the Court of Appeal on June 11th, when the Master of the Rolls upheld the judgment of the Aberdare county-court judge who had made an award in favour of a collier under the Workmen's Compensation Act, 1897, under the following circumstances. In the course of his work some coal trucks slipped back upon the collier and though he worked for a few days it was subsequently found that he was ruptured, but when being operated upon at the hospital a hernia of old standing was discovered and the colliery company from whom compensation was claimed contended that but for the prior lesion there would have been no further injury. A contrary opinion, as already indicated, was held by the local judge and by the Master of the Rolls.

Vaccination Questions.

The anxiety which is being displayed by boards of guardians in various parts of England and Wales to limit the services of the public vaccinator to the poorer classes will in some quarters be used as an argument in favour of transferring the administration of the Vaccination Acts from the Poor-law authority to the sanitary authority. In a recent report upon the subject the medical officer of health of Cardiff (Dr. Edward Walford) says that he has every reason to believe that the Cardiff board of guardians carries out the Vaccination Acts in a conscientious manner, but he is of opinion that the reasons which in 1840 decided Parliament to place the administration of the Acts in the hands of the boards of guardians no longer exist, for the matters connected with the prevention of disease are now under the jurisdiction of another and distinct authority which does not, however, control the most important measure connected with the prevention of small-pox. Dr. Walford states that at the time of the Gloucester epidemic he endeavoured unsuccessfully to prevail upon the Cardiff board to appoint temporarily additional vaccination officers with a view to discovering evasions of the Vaccination Acts and to induce adults to be revaccinated, and he was obliged, therefore, to instruct the sanitary inspectors to make special inquiries as to the condition of vaccination at houses visited by them and to forward the results of their inquiries to the vaccination officers.

The Destruction of Rats on Board Ship.

A demonstration was lately given at Cardiff of the Clayton apparatus for destroying rats on board ship and for disinfecting purposes. Sulphur dioxide gas (SO_2) and, it is claimed, also a small quantity of the higher oxide (SO_3) were forced into the bottom of a vessel's hold which had a capacity of 200,000 cubic feet; the foul air displaced by the gas was exhausted through a pipe communicating with the hold almost flush with the deck and conveyed to a furnace having a temperature of about 600° F. Rats in cages at the bottom of the hold died almost immediately after exposure to the gas and others placed about six feet below the level of the deck were found dead within three hours of exposure. To test the germicidal action Dr. W. G. Savage of the Cardiff and County Public Health Laboratory placed in the hold liquid cultures, soaked in strips of fabric, of the bacteria of plague, cholera, typhoid fever, and anthrax, and of staphylococcus pyogenes aureus. Three separate pieces of fabric were used for each variety of micro organism and subsequent investigation showed that all the plague, cholera, and typhoid fever bacilli were killed, but that none of the anthrax cultures were affected and one of the staphylococci cultures remained alive. These results are similar to those arrived at by Klein, Houston, and Gordon in the *London County Council* experiments.

The Covering of Meat during Transit

Among the by-laws made by the Glamorganshire County Council for "the good rule and government" of the county is one which requires that meat shall be well-covered over when being conveyed from one part of the county to another. On June 9th a man was fined 5*s.* at the Ton police-court for contravening this by-law which the stipendiary magistrate stated ought to be strictly enforced.

Death of Mr. Henry Marcus Kemmis, L.R.C.P. Irel., M.R.C.S. Eng., J.P.

Through the death from pneumonia on June 12th of Mr. Henry Marcus Kemmis the medical profession in Bridgwater has lost one of its oldest and most respected members. Mr. Kemmis had practised in Bridgwater for a quarter of a century and at the time of his death was one of the honorary surgeons to the *Bridgwater* Infirmary and medical officer to the workhouse. He was on the commission of the peace for the borough and was an enthusiastic volunteer, holding the rank of brigade-surgeon-lieutenant-colonel in the Severn Volunteer Infantry Brigade.

The Okehampton (Devon) Board of Guardians and Revaccination.

At the meeting of the Okehampton board of guardians held on June 7th the clerk read the list of those persons in the union who had been revaccinated at the expense of the ratepayers. A gentleman sent a cheque for 7*s.* 6*d.* to the guardians, being the fee for revaccination. He stated in his letter "that he was quite unaware by being revaccinated he had gone on the rates." One of the guardians said that he considered that a fuss was being made about nothing, as the Local Government Board Order distinctly stated that persons could be revaccinated at the public expense. After some discussion upon the fees for revaccination it was decided to inform the public vaccinators that they should ask persons applying for revaccination whether they wished it performed at the public expense or otherwise.

---

[1] THE LANCET, May 24th, 1902, p. 1501

Vaccination in the West of England.

At the meeting of the Helston board of guardians held on June 9th the finance committee recommended that all the old vaccination stations should be made stations for revaccination purposes, also that revaccination should be carried out only on receipt of seven days' notice from the clerk that the guardians considered it expedient, and that a fee of *3s. 6d.* should be paid for all cases of revaccination at all stations. The guardians decided to adopt the recommendations.

Oysters and Enteric Fever.

At the last meeting of the East Kerrier (Cornwall) District Council a letter was read from the Local Government Board stating that "the Board were informed that the liability of the oyster-beds in the Penryn river to contamination by sewage is well known to the local sanitary authorities in whose jurisdiction the river is situated, but the Board do not understand those authorities have taken any united action in dealing with the sewage discharged in the river and it does not appear that they have brought pressure to bear on the local oyster merchants to remove their 'market layings' to some locality free from danger. Consequently the Local Government Board will bring the whole of the matter specially to the notice of the Royal Commission on Sewage Disposal." The members of the council decided to take no action.

The Bristol General Hospital.

A fête and gymkhana, which was unfortunately held in unfavourable weather, took place at the Zoological Gardens, Clifton, on June 12th, 13th, 14th, and 16th, in aid of the funds of the Bristol General Hospital.—Lady Smyth of Ashton Court has given £1500 to the Bristol General Hospital, to be devoted to the endowment of a bed in memory of her late husband, Sir Greville Smyth.

June 16th.

IRELAND.

(From our own Correspondents.)

The late Dr. Barry of Limerick.

An action for £5000 damages in compensation for the death of the late Dr. Robert Barry of Limerick was recently brought by his widow and, after being tried before the Lord Chief Justice of Ireland and a special jury of the city of Dublin, resulted on June 16th in a verdict for the plaintiff for £3000. Dr. Barry, who died as alleged from an injury caused by the carelessness of one of the servants of Messrs. Spaight and Co., was a graduate and M.D. of the Royal University of Ireland and a Fellow of the Royal College of Surgeons in Ireland. He was well known and much respected in the city of Limerick.

Death of Mr. James Picken, L.R.C.P. & S. Edin.

I regret to announce the death of Mr. James Picken at his residence, Hazelbank, Randalstown, co. Antrim, which occurred on June 9th. For many years Mr. Picken had been dispensary medical officer of the Toomebridge district, but owing to delicate health he retired a few years ago from practice. A faithful physician, extremely kind to the poor, Mr. Picken secured the confidence of all those who found it necessary to have his professional advice. He leaves a widow and three sons to mourn his death.

Tyrone and Fermanagh Asylum.

At the monthly meeting of the committee of management of this asylum held on June 12th Dr. P. O'Doherty (Dublin) was appointed assistant medical officer at a salary of £125 per annum, with the usual allowances.

The Antrim Infirmary, Lisburn.

Dr. W. Calwell (Belfast) has been appointed consulting physician and Dr. Cecil E. Shaw (Belfast) consulting ophthalmic surgeon to the County Antrim Infirmary, Lisburn.

Ulster Medical Society.

The annual meeting of the members of the Ulster Medical Society was held in the Belfast Museum on the evening of June 12th when, after the reports of the treasurer, librarian, pathological secretaries, and council had been received, the members proceeded to consider the rules of the society which had been revised by a special committee in consequence of the gift of a new medical institute by the president, Professor W. Whitla. These rules, with a few verbal alterations, were passed and the donor of the new institute, Professor Whitla, read the trust deed and nominated seven trustees, all members of the society, in whom the property of the institute is to be vested and who will be *ex-officio* members of the council. The following office-bearers were then elected by the members themselves for the session 1902–1903:—President: Dr. John Campbell. Vice-Presidents: Dr. S. Agnew (Lurgan) and Dr. J. J. Austin. Secretary: Dr. Thomas Houston. Treasurer: Dr. W. B. McQuitty. Pathological Secretary: Professor J. L. Smith. Librarian: Dr. R. R. L. Leathem. Council: Dr. J. S. Morrow, Professor J. W. Byers, Dr. A. Gardner Robb, Dr. J. Colville, Dr. W. D. Donnan (Holywood), and Dr. J. B. Moore.

The Royal Commission on Irish University Education.

The Royal Commission on Irish University Education sat in Dublin during last week and heard evidence from numerous witnesses and amongst these were the Provost of Trinity College, Dublin. It is rumoured now that it is found impossible to leave Trinity College outside the purview of the Commission. At a meeting of the Royal University Graduates' Association held in Belfast on June 10th very strong resolutions were passed in reference to the treatment meted out to Mr. F. H. O'Donnell, M.A., by the Commission. It is stated that when he appeared to give evidence on May 22nd, in reply to a tardy request by the Commission, no attempt was made to elicit evidence by any of the Commissioners, notwithstanding that his book on the "Ruin of Irish Education" had been received by the Commission and that he had furnished a summary of the evidence he intended to give. The council of the Graduates' Association says that it is forced to the conclusion that there was some extraordinary influence hostile to a full hearing of the facts and to their official record in the blue-book. It is said now that no final report will be ready before October.

Small-pox in Belfast.

Both amusement and indignation are felt in Belfast at the publication of a very exaggerated and alarming report in the London *Daily Mail* of June 14th, headed "Small-pox panic," "Extraordinary terror and boycott at Belfast." The facts about the small-pox outbreak are these. The first case occurred in Belfast Gaol on March 13th and was the case of a man who brought the disease from Glasgow; the next was the case of a woman who contracted the disease in Liverpool from where she returned to Belfast. Both these patients were placed in the Union Hospital, Belfast, and within the hospital surroundings itself 17 cases have since developed, and within the last 10 days there has been no fresh case in the hospital. The inmates of the workhouse have been revaccinated and the most vigorous measures have been taken in the way of disinfection and observation. While this has been going on in the workhouse only four cases of small-pox (two of these were in a street adjacent to the workhouse) have arisen in the city of Belfast, the population of which is 350,000. These figures show that the report about a small-pox epidemic in Belfast has been greatly magnified. The statements in the *Daily Mail* are not only grossly exaggerated but they are positively harmful, as if not contradicted they will lead to a boycott of tourist traffic this season in Belfast and the north of Ireland.

The late Dr. William Thomson of Anahilt.

An appeal has been drawn up and circulated on behalf of the widow and family of the late Dr. Thomson of Anahilt, co. Down, who have found themselves deprived of their only means of support. Owing to his district being a poor one Dr. Thomson was unable to make any provision for his family. Dr. J. G. Jefferson, Lisburn, is treasurer of the fund.

Unveiling of a Mural Tablet erected in Memory of the late Professor Stephen O'Sullivan at the Cork North Infirmary.

The unveiling of a mural tablet erected to the memory of the late Professor O'Sullivan by the staff of the Cork North Infirmary took place in presence of a number of distinguished citizens in the main hall of the Infirmary. Mr. D. D. Donovan, senior physician, in a very interesting speech, mentioned that Professor O'Sullivan had been 40 years connected with the hospital. He referred to Professor O'Sullivan's distinguished career as a surgeon and the unselfish manner in which he consumption of milk supplied from the Helsarmel dairy to the former." At the dairy the well water was shown to be practically sewage and it was highly offensive at the time of calling—in fact, the sewage of a number of houses and the drainage water of a cemetery soaked into it, and Dr. Ashburton Thompson was able, moreover, to show that it was specifically infected from the excreta of a recent case of typhoid fever in the neighbourhood.

Dr. Page reported in 1888 that an outbreak of typhoid fever at Spennymoor (Durham) was associated in time with prevalence of fever at a farmhouse whence milk was distributed to a considerable number of the persons attacked. Dr. Bruce Low reported on an outbreak at Shildon and East Thickley (Durham) in 1893. There were scattered imported cases during May, June, and July, followed by a considerable outburst of the disease in August and September, the number of cases gradually diminishing in October and November. "The earlier cases were mild, anomalous, and irregular, the later cases typical and severe. Many cases admittedly escaped disinfection and established foci of infection." A large share in the diffusion of the disease was attributed to a particular milk service. "In the milk-seller's house there occurred three or four unnotified cases believed to have been enteric fever. The dairy where the milk was stored communicated directly with the sewer, without a bend or trap, by means of a four-inch pipe in the sink stone. History of flooding of milkman's cellar by sewage on two occasions in July after heavy rainfall. The public water-supply had nothing to do with the outbreak."

In 1895 Dr. Bruce Low reported on a sudden outburst of typhoid fever in August in the town of Helmsley, North Riding (Staffs.), confined to the customers of a particular milk-seller, a member of whose family recovering from this fever came on a visit to his house from July 11th to August 24th. The outbreak suddenly terminated in September on the stoppage of the sale of the polluted milk.

At the International Medical Congress of 1881 Mr. Ernest Hart read a paper on the Influence of Milk in Spreading Zymotic Disease in which he placed on record 73 outbreaks of disease as having been traced to the agency of milk, and of these no less than 50 were outbreaks of typhoid fever; and in 1897 he published another report on the same subject in the *British Medical Journal*, giving short accounts of 95 more outbreaks (occurring between 1882 and 1896), of which 48 were those of typhoid fever, making together 98 outbreaks of typhoid fever traced to the agency of milk by the end of the year 1896.

Dr. D. S. Davies, medical officer of health of the city of Bristol, read an important paper before the Epidemiological Society in March, 1898, on an Outbreak of Milk-borne Enteric Fever in Clifton. In this outbreak the cases varied from the mildest, which would not otherwise have been recognised as typhoid fever cases at all, to the severest type of the disease, mild and severe cases being found in the same houses. The outbreak, as is so often the case with those due to milk, showed an excess of attacks among children under 15 years of age. There were 244 cases in all, of which 230 "were shown to have obtained either regular or occasional supplies from one or other of the three infected rounds." Of the remaining 14 cases four were accounted for in other ways. The connexion of the fever with certain milk-supplies may be considered to have been established without a doubt.

In 1899 Dr. W. W. E Fletcher reported on an outbreak at Coleford (Gloucestershire), which place was almost free from typhoid fever from 1895 to 1898, when an outbreak occurred which he found to have been "intimately connected with one particular milk-supply."

In May, 1900, Dr. Fletcher reported to the Local Government Board on an outbreak of typhoid fever in the Urban District of Coleford and in the Rural District of West Dean (Gloucestershire). Dr. P. Buchanan, the local medical officer of health, had already ascertained that "although the drainage and sewerage of the towns are highly unsatisfactory and the polluted state of the water-courses dangerous to health, the outbreak was caused by contaminated milk; there was some difficulty in ascertaining how the milk had become contaminated. It appears most probable to have been either by washing the milk cans with polluted water from a well or by the fact that one of the workers in the dairy suffered from a mild attack of typhoid fever and that the milk he distributed somehow became infected from him."

In the twenty-sixth report of the State Board of Health of Massachusetts for 1894 Dr. William T. Sedgwick reports on an outbreak at Marlborough as follows: "While a very brief investigation had established the fact that the epidemic could not possibly be attributed to the public system of water-supply or sewerage the true source of the outbreak still remained to be found and I next turned to the milk-supply as a possible vehicle of the disease. But it soon became plain that many different milkmen were involved and that therefore ordinary milk could not have been the common carrier of the infection. Closer inquiry, however, finally disclosed the fact that very nearly in the middle of the infected district was a 'creamery' which, although private, served in a manner as a milk-centre for the whole city. This creamery bought milk from 28 different farms which constituted its regular supply. It also bought from time to time from the various independent milk-pedlers whatever milk they had left over and wished to sell after their daily rounds. On the other hand, the creamery sold to the various milk-pedlers whenever their own supplies 'ran short' and in these ways served, as it were, as a kind of 'clearing-house' for the milk-supply of Marlborough. My suspicions at once rested, largely because of its central location among the cases, on the creamery and very soon after upon this special skimmed-milk service. I therefore made in the next place a house-to-house investigation which established beyond all possible doubt the fact that there was a common bond existing between most of the cases. It had not escaped observation that the disease was confined to those of slender means or in poor circumstances, and closer investigation showed that some who had attempted to economise in their milk-supply by using skimmed milk had suffered most severely." He ultimately satisfied himself that this skimmed milk was the cause of the epidemic and concludes his report with the following observations: "As far as I know the present is the first case on record in America in which an epidemic of typhoid fever has been apparently due to the use of infected skimmed milk; but it is easy to believe that many obscure outbreaks of this disease may have come from a similar source. With the multiplication of creameries to which milk (or cream) is brought from numerous and various farms the possibility must be kept in mind of contamination of the whole product by one infected contributory portion; and inasmuch as skimmed or 'separated' milk, on account of its cheapness and freshness, is now much used not only for cooking but also for drinking, this product, as well as the 'whole' milk, must henceforth be regarded as a possible vehicle of infectious disease."

Dr. Pistor of Berlin has kindly forwarded me copies of papers from which I extract the following:—

I. Dr. Ricken of Malmedy (Rhine Province), writing on Typhoid Fever and Dairies, cites several instances of outbreaks traced to polluted milk; thus at a place called Reuland a general distributing dairy for skim-milk was established in 1897, and an outbreak soon occurred producing 73 cases in 36 houses, with 10 deaths; of these 22 houses were supplied by the dairy; moreover, all the families of the employés of the dairy, except one, suffered from the disease and in each village where an employé lived it was in that family that the disease first broke out. At Büllingen a dairy was opened in April, 1899, and an outbreak soon occurred and was traced to the dairy having been supplied from four houses where there had been cases of typhoid fever shortly before. The results are stated as follows:—(*a*) Of 316 houses of customers of the dairy 48 were attacked, or 15·2 per cent. (*b*) Of 210 houses not served by the dairy 20 were attacked, or 9·5 per cent., while in one of the villages (Wirtzfeld) of 34 houses of customers of the dairy 10 were attacked, or 29 5 per cent., and of 50 houses not served by the dairy eight were attacked, or 16 per cent. Moreover, of the 116 cases in this village no less than 35 were children under 15 years of age. At Nidrum, in the district of Malmedy, an outbreak among the soldiers of the camp of Eisenborn which recently took place was traced to the use of infected milk, supposed to have been sterilised but evidently not efficiently so. The way in which the milk became infected was not traced but typhoid has been endemic in the district for some years. At Auro (district of Prüm in the Eiffel) in 1898 a widespread outbreak was attributed to skim-milk distributed from the dairy there, because all the cases occurred in houses supplied by that dairy. In 1899 another outbreak occurred at Bleialf in the district of Prüm and was traced to another dairy (Zeitschrift für Medizinalbeamte, Heft ii., 1901).

II. Dr. Schlegtendal of Aix-la-Chapelle has collected accounts of outbreaks traced to polluted milk-supplies in Strasburg, the Canton Lucerne, Connecticut, Montclair had often devoted many hours daily to the services of the hospital where his great experience was always at the disposal of his colleagues. Professor C. Y. Pearson in a few words endorsed all that had been so well said by Mr Donovan. The Rev. Mr. Wilson, one of the governors of the hospital, also bore testimony to the invaluable services rendered to the hospital by the late Professor O'Sullivan and eulogised Professor O'Sullivan's unvarying kindness to the poor. The City High Sheriff (Mr. Augustine Roche) then unveiled the tablet and Dr. J. Cotter, honorary secretary to the staff, read the inscription. The High Sheriff stated that it was a melancholy pleasure to him to take part in that ceremonial as he was well aware of Professor O'Sullivan's merits as a surgeon, and he personally knew that Professor O'Sullivan's great ability and experience were always available for the poor amongst whom he had laboured so long and so well. On the conclusion of the High Sheriff's sympathetic speech the proceedings terminated.

June 18th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Affairs at the Faculty of Medicine.

CERTAIN grave incidents occurring at the Faculty of Medicine have been much discussed since June 7th. Dr. Pupin, the secretary, who has held that post for 20 years, has been suspended, together with the cashier, M. Imoville, who has had charge of the accounts for 25 years. Of course, there was much talk about embezzlement, malversation, and the like, but the facts of the case as obtained from information received at the Faculty are as follows. For many years M. Imoville had been weak enough to make his subordinates advances on the security of their salaries. He was the more easily able to do this from the fact that certain of the professors who were often away or who were in no way pressed for money, used frequently to let their salaries remain unclaimed for some time. But the unhappy cashier fell a victim to his wish to be obliging. Many to whom he had advanced money forgot to pay him and some left the place altogether while still owing him the money advanced. Matters went from bad to worse and so last year, finding himself altogether cornered, he went to the secretary, whose goodness and readiness to serve anyone are proverbial in the Faculty and who is adored by all his staff. To him M. Imoville told the whole story, whereupon Dr. Pupin made the mistake of not immediately communicating with the dean, thus endeavouring to save the unhappy M. Imoville by giving him time to make good the deficit bit by bit. This, however, was but lost labour, for when M. Debove became aware of the deficit and wished to know the exact state of affairs the cat was soon out of the bag. M. Debove at once communicated with the Minister concerned and the cashier and the secretary, his responsible chief, were at once suspended. A searching inquiry is being held and M. Griset, chief clerk of the Education Department, has been appointed secretary of the Faculty in the room of Dr Pupin.

The Hospitals Nursing Staff.

M. Mourier, the director of the Assistance Publique, has recently laid before the Municipal Council a scheme dealing with the hospitals which it is proposed to pull down and to rebuild,[1] together with certain proposals concerning the nursing staff. It is certain that the position of the staff of the Paris hospitals (other than the medical staff) is deplorable. The nurses have to work for 14 or 15 hours a day and then have a short rest in a badly appointed dormitory. This state of matters, of course, reacts most injuriously on the patients. M. Mourier proposes to substitute female nurses in place of male nurses and he also wishes to divide the non-medical staff into two categories, the first to comprise the nurses proper and the second the staff of cooks, laundry-workers, and the like. This innovation will excite great interest, for it is evident that persons who are compelled to turn suddenly from cooking, scrubbing, and washing to the more delicate work of the care of sick cannot of necessity do their work in accordance with the notions of modern asepticism. All the medical staff will, of course, welcome the proposed change. As to the question of the supply of nurses it is proposed to substitute one training-school for those at present existing at the Salpêtrière, Bicêtre, the Pitié, and Lariboisière hospitals. At this school would-be nurses will be trained for two years before serving as nurses in a hospital. A committee nominated by the Assistance Publique is examining into this scheme which, it is estimated, will cost some 200,000 francs annually. This seems a large sum but it must be remembered that there are 5465 members of the honorary medical staff to be dealt with.

Alopecia of Dental Origin.

At the meeting of the Society of Dermatology and syphilography held on June 5th M Jacquet showed a patient who had been attacked by alopecia areata after having suffered from bilateral facial neuralgia. M. Jacquet had treated the alopecia without success and eventually discovered that his patient had three carious molars. A dentist was called in and he extracted two teeth and filled a third. Three days later the neuralgia which had lasted for one year had quite disappeared. 12 days later the patches of alopecia which were perfectly bare were covered with hair. M. Galippe, without wishing to criticise the theory proposed by M. Jacquet as to the dental origin of alopecia, reminded the meeting that so far no dentist appeared to have been struck by the coincidence of alopecia with dental lesions. For his own part he had never seen a case. M. Du Castel related the case of a lady who had consulted him about two patches of alopecia on the nape of her neck. A short time previous to their appearance she had had a tooth filled and the dentist had omitted to place a clean napkin under her head. She considered that she had caught the infection from the head rest. Now was this a case of contagion or was the alopecia the consequence of the dental operation? M. Brocq related a case in support of M Jacquet's contention. It was that of a little girl who had come under his care some two months ago for alopecia. During the first three weeks of her treatment nothing was done to her mouth and the patches of alopecia markedly increased. Now, however, her teeth were being carefully attended to, and while no new patches had developed the original patches had lessened in size.

June 16th.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

A Medical Council for Canada.

DR. T. G RODDICK'S Bill has received the sanction of both Houses of the Canadian Parliament. When the Bill was before the Senate an important amendment was proposed and carried which provides that no province should be represented in the council either by elected or appointed members until after the said Act had been adopted by the legislature of the province and had thereby accepted the registration under this board with the provincial board in lieu of the registration with the provincial board. Provision was also made for provinces withdrawing from the council. An additional clause was appended which provided that the Act should not interfere as conveying any power to open medical schools or give medical education. These arrangements were subsequently concurred in by the House of Commons. Dr Roddick well deserves the thanks of the Canadian profession for having carried this Bill through Parliament single-handed.

Montreal Foundling Hospital.

According to the annual report of the medical superintendent of the Montreal Foundling Hospital, 32 infants were in the institution on May 15th, 1901. During the past official year 159 were admitted, making a total of 191 for the year, an increase of 22 over the figures of the preceding year. The deaths numbered 112. The treasurer reported that the total receipts for the year amounted to $6503, and the expenditure to $4799.

Medical Item from Labrador.

Dr Wilfred Grenfell, the English physician who is devoting his life to the amelioration of the fishermen of Labrador, writes to a friend in Montreal stating that at the present time there is great destitution prevalent among the inhabitants. The work of this medical missionary ranges from treating a compound fracture to making a pair of boots from the skin of a freshly killed seal. In summer Dr. Grenfell makes his trips along the coast in the hospital ship *Strathcona*, while in winter time his tours are made on dog sleighs. He has recently established at St. Anthony on the north French shore the third hospital since he began work in that land several years ago.

---

[1] THE LANCET, May 10th, 1902, p. 1363.

Montreal Dispensary.

The fifty-second annual meeting of the Montreal Dispensary was held in that city recently and the secretary's report for the committee of management shows that during the past official year the applicants for treatment numbered 16,675, as follows: Roman Catholics, 11,643; Protestants, 4004; other creeds, mostly Jewish, 1028. Medically classified they were as follows: medical and surgical, 8505; eye and ear, 2069; women's diseases, 1725; nose and throat, 912; skin diseases, 1983; children, 1327; and dentistry, 154. The report stated that while 75 per cent. of the poor who received the benefits of the dispensary were Roman Catholics comparatively few of that creed subscribed to the institution.

Interesting Medico-legal Case.

A medico-legal case of some interest to the profession in the province of Ontario has recently been before the courts at St. Thomas. The action was brought by Mrs. Duncombe, widow of the late Mr. Truman W. Duncombe, L.R.C.P. Edin., against the Mutual Life Insurance Company of New York, who had refused payment of a $5000 policy on the ground of "fraud." Mr. Duncombe was a well-known practitioner of Western Ontario, a gentleman 40 years of age, and a medical examiner for the defendant company. He already held several policies in the company when he made the application on July 11th, 1901, for an additional $5000 policy. He filled in his own medical examination paper and got a brother practitioner to sign it who had examined and passed him previously for another company. After some hesitation the company accepted this policy although the examination had not been made by one of their own examiners. On Oct. 2nd in the same year Mr. Duncombe died suddenly and although the company paid all his other claims they refused to pay this one for the reason above mentioned; hence the action. The case hinged on the point whether Mr. Duncombe knew at the time that he wrote out his own examination paper that he was not in good health. It was clearly shown that he had not been examined by his brother practitioner on the date set forth in the examination form. No necropsy had been held after death, but the embalmer had noticed a swelling to the left side of the lower part of the sternum. He had drawn off one and three quarter pints of dark red blood which was clear and which clotted in the bottle. Under these circumstances the medical experts considered that death most probably had been due to rupture of a thoracic aneurysm and that the condition must have been present before Mr. Duncombe had made application for the insurance. The case was dismissed with costs.

The Public Health of Montreal.

The report of the Hygienic Committee of Montreal, for 1900, which has just been issued, deals with some interesting matters. As regards vaccination it shows that there were 6990 vaccinations performed during 1900, 48 only of which were reported as having been done by family physicians. The others were the work of three public vaccinators and of that number 30 per cent. were primary vaccinations. During the year there were 2802 cases of contagious diseases, as follows: diphtheria, 523; scarlet fever, 1107; typhoid fever, 647; and small-pox, 24. The births for the year were as follows: males, 4986; and females, 4906. 2240 marriages were solemnised. Of the 5287 deaths among the French Canadians in the city 3299 were those of children under five years of age; amongst the other Catholics 444 of the deaths were those of children under five years of age. Amongst the Protestants 307 deaths of children under five years of age took place. 55·95 per cent. of the total mortality in the city took place among children under five years of age, and 44 05 per cent. among children above five years of age.

Montreal Physicians Honoured.

A short time ago a complimentary banquet was given by the medical profession in Montreal to three of the oldest and most distinguished physicians of that city—namely, Dr Rottot, dean of Laval Medical College; Dr D. C. McCallum, emeritus professor in the Faculty of Medicine at McGill University; and Sir William Hingston, professor of clinical surgery at Laval. The occasion was the celebration of their golden jubilee in the ranks of medicine. Dr Rottot was admitted in 1847 a graduate of the old Montreal College of Medicine which later became the Victoria and now is the Medical Faculty of Laval; Dr. McCallum was graduated from McGill University in 1850 and for many years held the Chair of Obstetrics; and Sir William Hingston was a graduate in 1851 and has devoted himself almost entirely to surgery of late years. He has been mayor of Montreal and is a member of the Canadian Senate. Over 150 physicians of the city attended the banquet to do honour to these gentlemen.

University Intelligence.

Dr. Bovey, dean of the Faculty of Applied Science at McGill University, has been made a Fellow of the Royal Society of Great Britain. Dr. Bovey came to McGill University in 1872 as professor of civil engineering and applied mechanics. In the following year a department of applied science was instituted of which Dr. Bovey became dean. He has been dean ever since that time and under his able management the faculty has increased by leaps and bounds until to-day few science faculties in the world surpass it.—Dr. James Stewart of Montreal has been elected President of the Association of American Physicians at the annual meeting held recently at Philadelphia. Dr. Stewart is professor of medicine and of clinical medicine at McGill University. He is also physician to the Royal Victoria Hospital, Montreal.—Dr. G. P. Girdwood has tendered his resignation of the chair of Chemistry in the Faculty of Medicine at McGill University. This has been accepted and Dr. Girdwood has been appointed emeritus professor in the Faculty of Medicine. He was appointed professor of practical chemistry at McGill University in 1872 and of chemistry in 1879. He was one of the original Fellows of the Royal Society of Canada.—Dr. Wyatt Johnston has been appointed professor of hygiene in the Medical Faculty of McGill University in succession to Dr. Craik who has resigned.—Sir James Grant, M.D., Ottawa, has been elected President of the Royal Society of Canada. The annual meeting of the society was held recently at Toronto University.

Toronto, June 3rd.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Cholera in Manila.

THE outbreak of cholera in Manila which commenced in the middle of March still continues, although there are signs that the epidemic is on the wane. The fatalities from the disease have been nearly wholly confined to the native population; a few Europeans, however, have been stricken and have succumbed. The origin of the outbreak is attributed by the United States chief quarantine officer of the Philippines, Passed-Assistant-Surgeon J. C. Perry, to vegetables brought from Canton. Cholera is said to have existed in Canton for some time before its presence was reported and during this period the Canton vegetables were allowed to be landed in Manila. Manila is the greatest vegetable market of the Orient, as nothing of that character is produced in the Philippines. All such supplies have to be imported and all green vegetables, such as cabbage, celery, lettuce, and cauliflower, have come from the Canton districts. As soon as cholera was diagnosed with certainty the Board of Health of Manila took steps to combat the disease and to curtail its spread. Large detention camps and an elaborate system of inspection were rigidly carried out. Cases of cholera were sent to cholera hospitals' and all contacts and suspects were immediately removed to the detention camps, the infected house being at once disinfected, closed, and placed under guard. A cordon was immediately thrown round the city, ferry-boats and passenger trams were stopped, and all passengers going to the neighbouring provinces, either by rail or small boat, were required to secure a permit from the board of health. All the drinking-water from whatever source was strictly supervised and all green vegetables in the city and markets that were considered as liable to convey the disease were bought and destroyed. The city was also quarantined against the provinces.

New York Board of Health and Soft Coal.

The general strike in the anthracite coal regions has resulted in an extreme scarcity and consequent high price of hard coal in New York city. Many of the large business houses, hotels, and apartment houses of New York for the sake of economy have been burning for the past week bituminous coal which has had an unpleasant effect on the atmosphere. Dr Lederle, the present head of the New York Health Department, has taken cognisance of the matter and has sent out a large number of inspectors to locate the establishments whence the soft-coal smoke proceeds. Section 134 of the Sanitary Code makes it a civil offence for a householder to allow smoke other than white or cinders, dust, gas, or any offensive odour to come from his chimney "Notice will be sent to all persons guilty of the offence to discontinue the use of soft coal within five days and in aggravated cases within 24 hours If the notices are not heeded they will be prosecuted under the afore-mentioned section of the code on a civil charge and in case of the smoke blowing into neighbouring windows the offenders will be held on a criminal charge."

Retirement of Surgeon General Sternberg

Surgeon-General Sternberg will shortly be retired for age from the command of the medical department of the United States Army It is proposed that Dr Sternberg shall be retired with the rank and pay of major general. A Bill to that effect has been favourably reported to the United States Senate by the Committee on Military Affairs. The *American Journal of Military Surgery*, referring to General Sternberg's retirement, says, "The practical and potentially entire extirpation of yellow fever is but one of many scientific and humanitarian acts, rendered possible by his devotion to duty in its broadest and highest sense. With executive capacity of the soundest type, his administration of the enormous business affairs of his office has been characterised by exceptional sagacity and skill, while the military phases of his command have continued to progress with cumulative advantage to the service. General Sternberg's incumbency of the surgeon generalcy, indeed, has been continuously marked by lofty aims and results so beneficial to the army and to the country that his promotion to the grade of major-general prior to his retirement for age would be but a slight recognition of his worth."

Suicide in Chicago

Chicago has always borne a somewhat evil reputation as a city given over to a wearing, rushing, nerve-straining existence and consequently its inhabitants have been esteemed a short-lived race. It now appears that such is not the case, and the bulletin of the Chicago Health Department for the week ending May 24th shows that, on the contrary, Chicago is an exceptionally healthy city and that with the exception of a remarkable tendency to suicide exhibited by its population the metropolis of the West compares favourably in the matter of health with any city of the United States. Deaths by violence have greatly decreased and there has been a decrease of 6 7 in cases of homicide and manslaughter Railway and street-car accidents have also considerably diminished in number The sole blot on this fair picture is the increasing frequency of suicides in Chicago. From 1880–90 inclusive there were 1272 suicides out of 7898 cases of death by violence and there have been 166 cases of suicide since Jan. 1st of this year, an increase of 10 per cent. over the number for the corresponding period of 1901. The Health Department of Chicago some time ago attributed this suicidal tendency to influenza and in the bulletin referred to reiterates the belief in the following words "The relation, as cause and effect, of influenza and suicide is clearly demonstrated by a further study of the figures The fourth great epidemic of influenza in this country began in December, 1889, since which time Chicago has never been entirely free from its infection" Influenza has a peculiarly potent effect upon the nervous system and undoubtedly predisposes its subjects to various forms of brain affections from melancholia to suicidal impulse. It has often been remarked before that influenza is frequently followed by almost uncontrollable suicidal tendencies, and the Chicago Health Department is probably right in ascribing to this cause the increase of suicide in that city

American Congress on Tuberculosis.

This congress opened at the Hotel Majestic, New York City, on June 2nd and lasted for three days. The most important papers, probably, were those read by Dr H. Edwin Lewis, secretary to the committee, and by Dr Adami, professor of pathology in McGill University, Montreal, on the Intercommunicability of Human and Bovine Tuberculosis and the Menace to the Public Health of Impure Milk. Dr Lewis protested against the extreme importance attributed to bacilli in the causation of consumption and argued that efforts are too much directed towards the extinction of the micro-organisms and too little attention is paid to the patient. He then went on to give his views as to the relation of metabolism to human susceptibility Dr Adami in reference to the danger arising from the consumption of impure milk by children, said "As a point upon which we are in absolute agreement it may be set down that under ordinary conditions tuberculosis of domestic animals does not develop by reason of infection from human beings suffering from the disease. The infection is from animal to animal.

Is the existence of tuberculosis among livestock a menace to the farming industry in this country? Undoubtedly it is, and that not so much because here in America the herds are already very extensively affected as because of its great tendency to spread. It cannot be too strongly emphasised in connexion with impure milk that our danger lies in its liability to set up gastro-enteritis in those drinking it, or, in plainer words, acute digestive disturbances, especially in young children I do not know if you appreciate the terrible mortality—one far exceeding that from tuberculosis however produced—which there is among children from six months to one year, a mortality which can only be put down to the consumption of milk which is crowded with acid producing putrefactive germs"

June 9th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT)

The Plague

THE bubonic plague continues its course in Sydney and Brisbane at about the same rate. Every week several cases occur, last week, for instance, in Sydney seven cases were reported, one patient died and four were discharged from hospital, where 32 remain. In Brisbane three or four cases occur weekly No cases have been reported from the other states. A curious development has taken place in Sydney where the animals at the Zoological Gardens have been severely attacked by plague, especially the kangaroos and wallabies, since April 3rd 19 animals and two birds have died. It is supposed that the disease spread to them by the medium of fleas from plague-infected rats. This is the first known infection of marsupials with bubonic plague. The gardens have been closed and all the premises in which the animals are housed have been cleansed and disinfected. One of the difficulties in dealing with the plague in Sydney is the existence of old sewers, laid down in early days, the plans of which have been lost. Most of them are in disuse but at low levels and consequently full of filth. All, moreover, act as nurseries for rats, and the Mayor of Sydney stated recently his opinion that the plague will never be stamped out till these old sewers are abolished. But, as is usually the case in 'board-ridden Sydney," there is conflict of opinion as to whether action should be taken by the city council, the Water and Sewerage Board, or the Public Works Department of the Government.

Friendly Societies and Medical Contracts.

A conference was recently held between delegates from the friendly societies in the western suburbs of Sydney and from the Western Suburbs Medical Association to consider a proposal to have one uniform medical contract in use in all lodges in the district A draft contract was submitted and discussed and a copy sent to each lodge for consideration of its members, after which a second conference will be held.

Hospital Affairs

The "imbroglio at the Women's Hospital," Melbourne, to quote the newspaper headings is slowly resolving itself The committee declined to re-instate the dismissed resident medical officers and called for applications. Only one was received, from Mrs. Martell, M B., a former resident, who was appointed Then another difficulty arose. Dr Muir, the resident medical officer in the infirmary department of the hospital, declined to relieve Dr Martell and to obey the rule of the hospital that only one of the responsible officers of the hospital shall be absent at a time, saying that it had never previously been enforced and was regarded as obsolete. It is understood that a compromise is being arranged but no applications have been sent in for the position of junior medical officer to the midwifery department.—At the Melbourne Hospital the accounts for the first quarter of the year show a deficiency of over £600 The committee states that if expense is to be further reduced it can only be done by closing some of the wards, although the accommodation is not at present nearly sufficient to meet the demands made on it. It is suggested that more should be contributed by the municipalities. Dr. J. W. Barrett has been appointed consulting oculist and Dr. W. K. Hughes consulting aurist to the hospital. Plans have been prepared for the new sanatorium for consumptives to be erected at Wentworth, New South Wales. The buildings provide for 20 patients in three pavilions and two night-room cottages. The sanatorium is to be completed in five months. 24 applications have been received for the position of resident medical officer, at a salary of £300 per annum, with board and residence; of these, none were from Australia, 15 were from Great Britain, four from Germany, four from the United States, and one from Fiji.

Nurses' Examinations.

A conference was recently held of representatives from the Melbourne Hospital, Alfred Hospital, Melbourne Children's Hospital, and Victorian Trained Nurses' Association to arrange for a uniform standard of instruction and examination for nurses and the appointment of a conjoint board of examiners in the final subject of nursing. The proposals were agreed to and it was decided that the committees of the three hospitals represented should nominate a member of the honorary medical staff and the Nurses' Association, two medical men to form the conjoint board. Dr. Thomas Cherry, lecturer on bacteriology at the Melbourne University, has been appointed bacteriologist and scientific daily expert to the Agricultural Department of Victoria. He is to receive a salary of £600 a year and travelling expenses. He will continue to control the bacteriological laboratory at the University, but a demonstrator and assistant lecturer will be appointed to assist in the university teaching.

Obituary.

Dr. William Snowball, who died on April 22nd, was the first in Victoria to make the study and treatment of children's disease a specialism. He had a marked personality and was a capable and exceedingly successful practitioner. He was born in Carlton, a suburb of Melbourne, where he passed the greater part of his life and was only 47 years of age at his death On leaving the Church of England Grammar School he entered the Medical School of the Melbourne University, where he passed his final examination for the M.B. degree before the statutory age of 21 years and had to wait some time before graduating in 1875 He subsequently visited Europe and studied more especially the diseases of children, and on his return he entered on that close association with the Melbourne Hospital for Sick Children which lasted till his death. When he was first appointed resident medical officer the hospital was a small affair conducted in a private house and the staff consisted of general practitioners. Very largely as the result of Dr. Snowball's indefatigable efforts the hospital extended its operations and the specialism became more and more defined. At the same time Dr. Snowball himself became the acknowledged authority on children's diseases in Australia and had an immense and lucrative practice. He was a man of great natural sympathy, tact, and intuition, that enabled him to manage his little patients with marked success. He was an omnivorous reader of all kinds of literature and very catholic in his tastes One of his greatest pleasures was to help his younger brethren in the profession, and during his whole career the Children's Hospital was always first in his thoughts, and his large private practice was never allowed to interfere with his attendance at the hospital.—The late Robert Denham Pinnock, M.D.Glasg., who died suddenly while on a shooting excursion, was for many years the leading medical practitioner in Ballarat. He was born near Melbourne in 1849, was educated in that city, but graduated as M D. at Glasgow. He settled in Ballarat on his return to Victoria and soon established a large and lucrative practice. He was for years on the honorary staff of the Ballarat Hospital and was a capable surgeon, though conducting a general practice. He took a prominent interest in public affairs, was a vice-president of the school of mines, and a member of the council of the art gallery. For many years he held a commission in the militia He was extremely popular both with the profession and the public and will be a great loss to Ballarat.—Dr. Sydney Henry Schrader of Waverley, New South Wales, died on March 26th after a protracted illness at the early age of 36 years. He was a native of New South Wales and the son of a medical man. He studied medicine in the University of California, U.S.A., where he took his M.D. degree in 1893. He commenced practice in Narrabri in partnership with Dr. Henry and seven years ago moved to Waverley where he had an extensive practice. He held the rank of captain in the Royal Army Medical Corps and was attached to the Engineers. He was also an enthusiastic supporter of the game of bowls. He left a widow but no children.

May 8th.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At examinations for medical and surgical degrees, Easter term, the following candidates were successful:—

SECOND EXAMINATION.

Part I., Pharmaceutical Chemistry.—H. E. T. Dawes, St. John's; G. B. Fleming, King's; H. A. Hancock, non-collegiate; V. C. Honeybourne and R. McC. Linnell, St. John's; C. H. Rippmann, B.A., King's; H. A. Smith, B.A., H. Selwyn; F. J. Thornton, Caius; and D. R. P. Walther, Pembroke.

THIRD EXAMINATION (NEW REGULATIONS).

Part I., Pharmacology and General Pathology.—H. C. Cameron, B.A, St. John's; H. M. Clarke, B.A., Clare; D. R. T. Clarkson, M.A., H. Selwyn; R. P. Cockin, B.A., Caius; H. Dodson, B.A., Downing; W. G. P. Ellis, M.A., Catharine; H. Falk, B.A., King's; H. J. Fardon, B A., Christ's; G. R. Footner, B.A., Pembroke; E. Gardner, B.A., Caius; C. B. Goulden, B.A., Non-Collegiate; F. W. Goyder, B.A, and J. R. C. Greenlees, B.A., St. John's; G. H. Harper-Smith, B.A., Caius; C. King, B.A., Trinity; G. H. K. Macalister, B.A., and O. V. Payne, B.A., St. John's; W. H. Robinson, B.A., Downing; C. T. Y. Robson, M.A., St. John's; E. W. Sheaf, B.A., Downing; and G. C. E. Simpson and G. A. Ticehurst, B.A., St. John's.

FREEMASONRY.—*Rahere Lodge, No 2546.*—The installation meeting of this Lodge was held in the Great Hall of St. Bartholomew's Hospital (kindly lent for the occasion by the treasurer and almoners) on June 10th. Mr. John C. Baker, M.B. Lond., and Mr. Wilfrid H. W. Attlee, M.B. Cantab., were initiated into Freemasonry and Bros. Cross, Griffith, and Drysdale were elected members of the Standing Committee. W. Bro. Phineas S. Abraham, M.D. Dub., the outgoing W.M., installed his successor, Bro. George H. R. Holden, M.D. Cantab., as W.M. for the ensuing year. W. Bro. Holden then invested as his officers: W. Bro. Ernest Clarke. F.R.C S. Eng., S.W; W. Bro. J. H. Gilbertson, P.P.G.D. Herts, J.W.; W. Bro. the Rev. Sir Borradaile Savory, Bart., P.G C., Chaplain; W. Bro. Clement Godson, P.G.D., M.D. Aberd., Treasurer; W. Bro D'Arcy Power, P.G.D., F.R.C.S, Eng, Secretary; Bro. H. J. Waring, F.R.C.S. Eng., S.D.; W. Bro. W. Haig Brodie, P.P.G.D. Surrey, M.D. Edin., J D.; W. Bro. F. Swinford Edwards, P.M., F.R.C.S. Eng., Director of Ceremonies; Bro. J. H. Drysdale, Assistant Director of Ceremonies; Bro. G. H. Robinson, Mus. Bac., Organist; Bro. H. W. C. Austen, M.D. Lond., I.G.; Bro. M. J. Anderson, Steward; and Bro. W. H. Cross, Bro. O. H. Cosens, Bro. M. L. Trechmann, F.R.C.S. Eng, and Bro. S. R. Scott, Assistant Stewards. The lodge passed a resolution approving of the formation of a Royal Arch Chapter of the Hospital Lodges to be affiliated to the Rahere Lodge and appointed W. Bros. Holden and D'Arcy Power to serve as representatives on a sub-committee to carry the proposal into effect. A Past-Master's jewel was unanimously awarded to W. Bro. Abraham for his services to the Lodge during his year of office and presented by W. Bro. Holden. W. Bro. Abraham, in reply, expressed his sincere thanks. The report of the audit committee was received and adopted. It showed that the financial position of the Lodge was satisfactory and that the sum given away in charity during the past year amounted to £60 18*s.* A grant of £5 was unanimously voted as a first instalment for the benefit of a brother in distress. The brethren subsequently proceeded to Frascati's Restaurant where the banquet was held. The attendance was a large one and a most enjoyable evening was spent, an excellent entertainment being provided by Bro. Walter Churcher, Bro. Astley Weaver, and others.

FEEBLE-MINDED CHILDREN AND THE LONDON SCHOOL BOARD.—At the weekly meeting of the London School Board on June 12th it was decided on the recommendation of the General Purposes Committee to appoint Mrs. F. M. D. Berry, M.D., B S. Lond., as assistant (lady) medical officer, under the direction of the medical officer, at a salary of £250 per annum. Dr. Berry will be employed in the work of the medical officer's department, but chiefly in connexion with the examination of children requiring special instruction—viz., feeble-minded, crippled, blind, or deaf—and to examine all female teachers and officers in the board's service and candidates for appointment by the board.

THE DANGERS OF NICOTINE PROSECUTION BY THE PHARMACEUTICAL SOCIETY.—At the Kingston-on Thames County Bench on June 12th Joseph Hutchinson, seed and artificial manure merchant, appeared to answer three summonses for selling a poisonous vegetable alkaloid known as nicotine without having his name and address on the bottle, for selling the poison to an unknown person, and for failing to make an entry of the sale in a book kept for the purpose, contrary to the provisions of the Pharmacy Act, 1868. Mr. Vaughan Williams, in opening the case, said that the poison the defendant was charged with selling was contained in a compound known as "The XL All Vaporiser Fumigator," used for the destruction of insects in greenhouses, which was made up of a number of various kinds of poisons, but a two-ounce bottle contained sufficient nicotine to poison hundreds of persons.—Harry Moon, clerk to the Registrar of the Pharmaceutical Society, stated that there was a label on the bottle containing the following 'Tobacco is generally considered to have somewhat poisonous properties, and the juice of tobacco which collects in the stem of a pipe is well known to be poisonous. This compound contains the concentrated nicotine of tobacco and should be kept in a safe place and out of the reach of children."—Mr. Dobbs, addressing the magistrates for the defence, urged that an article of this kind which was sold for trade and technical purposes had been held to be exempt from the provisions of the Pharmacy Act. If it were not so the businesses of many tradesmen would be ruined and it would be vesting a monopoly in poisons in the hands of chemists, a thing that the Legislature never contemplated.—The magistrates having conferred in private the chairman said they considered the case proved and the defendant would be fined £2 on each of the three summonses, including costs. The bench consented to state a special case for the Court of Appeal.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

The Midwives Bill.

THE Midwives Bill has now passed through all its stages in the House of Commons and will not be seen again there unless the House of Lords makes some alterations in it. In that event it will be for the House of Commons to signify its approval or disapproval of the changes. In the House of Lords the measure will still be regarded as a private Member's Bill, but there can be no difficulty in finding time for its discussion. It was formally introduced on Monday, June 16th and put down in the name of the Duke of Northumberland for second reading on Friday, June 20th.

The Sale of Butterine.

The Bill introduced by Mr. Hanbury with reference to the sale of butterine extends to this article the margarine clauses of the Sale of Food and Drugs Act of 1899 with certain exceptions. For instance, it does not propose that the restriction upon the amount of butter fat in margarine shall apply to butterine and it says that the wrapper containing the butterine shall have a label indicating that the butter has been adulterated or impoverished and approximately to what extent.

HOUSE OF COMMONS.

WEDNESDAY, JUNE 11TH.

Scotland and the Conscientious Objector.

Mr WEIR asked the Lord Advocate if the Secretary for Scotland would consider the expediency of introducing legislation such as would admit of the Conscience Clause in the Vaccination Act of 1898 being extended to Scotland.—The LORD ADVOCATE replied: The Secretary for Scotland sees no reason for introducing legislation of the kind suggested by the honourable Member and cannot undertake to do so.

Sanitary Accommodation in Factories and Workshops.

Mr TENNANT asked the Home Secretary whether he had yet issued an order setting forth a standard of sanitary accommodation in factories and workshops; and, if so, whether he could lay it upon the table of the House.—Mr RITCHIE said: The consideration of this matter has necessitated a great deal of inquiry, but the chief inspector has now submitted his proposals, and although one or two points still require consideration I hope to be able to publish the draft order shortly.

The Use of Alcohol in Manufactures.

During the committee stage a clause was inserted in the Finance Bill enabling the Commissioners of Inland Revenue to exempt from duty after consideration of the circumstances of each case pure alcohol used in manufactures. The clause was brought forward by Mr HALDANE who explained that owing to the duty manufacturers in this country were placed at a great disadvantage in their competition with foreign manufacturers. He instanced the case of manufacturers of explosives and of drugs and perfumery. Nearly all the chloral used in this country had, he said, to be made abroad, whilst the export duty of chloroform made the cost of landing it in Australia to the British manufacturer double the cost to the German manufacturer. In the same way on account of the duty on pure alcohol much valuable research work had to be done abroad. With the clause in operation all this trouble might be obviated.

THURSDAY, JUNE 12TH.

Fees for Vaccination Exemption Certificates.

Mr SPENCER asked the Attorney-General whether his attention had been called to the variety of practice as to the charging of fees for a certificate of exemption from compulsory vaccination and as to the doubts which exist as to the payment of such fees and whether he could suggest any method for abolishing such fees.—Mr RITCHIE replied to the question saying: It is true that the fees referred to vary in different places; but so also, and to a greater extent, do other fees similarly fixed by tables prepared by local authorities. When the tables are submitted for the approval of the Secretary of State every effort is made to secure uniformity, but his power does not extend to enforcing it. I am not aware of any doubt as to the power of the local authorities to fix such fees. But I may say that the Northamptonshire Standing Joint Committee have recently submitted to me a table from which it would appear that they do not desire that such fees should be charged within their jurisdiction. The matter is receiving consideration.

Scotch Parish Councils and their Medical Officers.

Mr WEIR asked the Lord Advocate if the Secretary for Scotland would consider the expediency of recommending parish councils throughout the Highland crofting counties, by means of circular or otherwise, to make arrangements such as would admit of parochial medical officers obtaining an annual holiday as in other parts of the United Kingdom.—The LORD ADVOCATE: I am informed that this subject was considered by the Local Government Board in 1900 and that their views are fully stated in their report for that year at page 25. The Board do not propose to do more than is there stated.

FRIDAY, JUNE 13TH.

Cremation Bill.

This Bill was considered on report and was afterwards read a third time. It has already passed through the House of Lords.

TUESDAY, JUNE 17TH.

London Water Bill.

Mr LONG, in reply to a question as to the further procedure on the London Water Bill, said that on the return of the measure from the Joint Committee it would be considered in Committee of the whole House and would subsequently be treated as a public Bill. He could not at present say when the Bill would be taken.

Proposed Medal for Hospital Ship Crews.

Mr FORSTER asked the Secretary of State for War whether a medal had ever been issued to commemorate any war or warlike operations and granted to the masters and officers of transports or hospital ships; and, if so, whether, in view of the great services rendered to the country by the masters, officers, and crews of the transports and hospital ships employed during the war in South Africa, it was intended to grant to them the South African medal.—Mr BRODRICK replied: There are precedents for the award of medals to the masters of transports and hospital ships in a few exceptional cases. The question as to whether these precedents should be followed to any and, if so, to what extent in the case of the masters, officers, and crews of transports and hospital ships employed during the war in South Africa is at present under consideration and I am not as yet in a position to make a statement on the subject.

Hours of Women in the Fruit Preserving Trade.

Mr TALBOT asked the Home Secretary whether he would reconsider the Order issued by his authority for fruit preserving under the Factory and Workshop Act, 1901, with a view of preventing the undue employment of adult women for excessive hours under Article 5 of the Order, and extending the exception given by Article 6 of the Order to young persons under 18 instead of only to those under 16 years of age.—Mr RITCHIE replied: I think the Draft Order goes as far as it is safe to go at present. After a year or two of experience of its working it may be possible to make a further advance but even if I were satisfied that the honourable Member's suggestions were practicable I should hesitate to adopt them now at the cost of delaying for 40 days the bringing into operation of the new Order.

WEDNESDAY, JUNE 18TH.

Prison Medical Officers and their Duties.

Mr CONDON asked the Chief Secretary to the Lord Lieutenant of Ireland whether Mr Corr now a prisoner in Clonmel Gaol, under the Criminal Law and Procedure (Ireland) Act, applied on May 10th to the medical officer of the gaol for an hour's additional exercise on the ground of ill health caused by continued confinement in his cell; whether the doctor replied that he was a bail prisoner and could leave when he liked and that if he were in another class it would be a different matter; whether the governor told the doctor that Mr Corr could not leave as he was undergoing another sentence running concurrently with the bail sentence; whether the doctor refused the application; whether Mr Corr is still in solitary confinement; and whether medical officers of prisons were entitled under the prison rules to differentiate in their treatment of prisoners whether bail or otherwise.—Mr WYNDHAM replied: The application made by the prisoner on the 17th (not the 10th) May was not made on the ground of ill health. He complained of the confinement but stated that he was in good health, a statement with which the medical officer concurred. The doctor observed that it would be desirable to give bail if he wanted greater freedom as, unless on medical grounds, he could not interfere with prison rules. The doctor has no recollection of making a reference to his being in another class. The reply to the third query is in the affirmative. In reply to the fourth query, the doctor did not recommend an extension of exercise inasmuch as he was unable to do so on medical grounds. The prisoner is in solitary confinement only in the sense that he occupies like all other prisoners a separate cell. He is exercised in association with other prisoners of his class in the open air for two hours daily. In reply to the concluding inquiry medical officers are not so authorised except on medical grounds.

THE MIDWIVES BILL.

THIRD READING DEBATE: FULL REPORT.

ON Friday, June 13th, two hours of the time of the House of Commons were devoted to a debate on the motion for the third reading of the Midwives Bill. Before the debate began the opening sentence of the first clause was amended so as to make it clear that the Act as a whole will come into operation on Jan. 1st, 1905, and the penalty provision on Jan. 1st, 1910.

Mr. GRIFFITH BOSCAWEN said that while he did not intend to oppose the third reading he thought the Bill was so exceptional in its character that he could not allow it to pass without a few words. The Bill was contrary to the whole course of legislation on these questions. For many years past Parliament had endeavoured to strengthen the law against what he might call quack or inferior practitioners. In the present state of the Medical Acts no medical practitioner could practise midwifery unless he had qualified, not only in that subject, but also in medicine and surgery. Now this Bill entirely reversed that policy. Instead of making the qualification more strict it made it far more easy. It enabled people to practise who were only qualified in midwifery and he was afraid that in many cases their qualification would not be very high He quite recognised that there were special reasons why this course should be adopted. In the first place, although the law laid down these high qualifications for medical men, the fact remained that in practice the great bulk of the poorer classes did not resort in ordinary cases of labour to the medical profession but to midwives. Many of these women were ignorant, untrained, unregistered, and unregulated, and had been the cause of much suffering and mortality which was preventable. He apprehended that the reason why the poorer classes did not avail themselves of the services of medical men was that they could not afford to pay the charges, but he must point out that unless the amendment inserted during the report stage had been inserted the Bill would have been perfectly useless, because the unqualified and untaught practitioner would have been allowed to continue her practice and, just as now, the poorer classes would have gone to her instead of to the qualified person. Had the Bill passed in its original form the unregistered woman would have been preferred to the registered woman because of the cheaper charge of the former and thus the evil complained of would have continued. He admitted this and it was because of the acceptance of the amendment that he had withdrawn his opposition to the Bill. There had been strong objections pressed against this provision to prevent after Jan. 1st, 1910, uncertified women practising habitually and for gain and he had heard sinister rumours that attempts might be made to remove it when the Bill reached another place. He knew that the Home Secretary spoke most strongly against it and that he felt most strongly against it and he told the House that for his part he could not accept the amendment He had thought a great deal about the speech of the Home Secretary and he failed to understand his objection The right hon. gentleman said that the amendment would prevent not merely the unregistered woman from nursing in a midwifery case but from watching the other children, cleaning the house, and performing other menial duties for a friend. He (Mr. Griffith Boscawen) could not see how that would follow. The words of the amendments were "habitually and for gain attend women in childbirth" What, therefore, was contemplated was the actual nursing and attending the women in the course of labour. If the words were not sufficiently clear they could be amended so that there should be no risk of interference with menial duties such as the Home Secretary had described.

Mr. JESSE COLLINGS Who is to pay?

Mr. GRIFFITH BOSCAWEN: The person who employs the woman must pay her.

Mr. JESSE COLLINGS: And he an agricultural labourer

Mr. GRIFFITH BOSCAWEN said that if the right hon. gentleman suggested that the agricultural labourer could not pay for this assistance the Bill was of no use He confessed that he should have liked to see the Central Midwives Board made a stronger body and he also thought that the local control ought to be stronger. He, however, did not oppose the Bill. At the same time it was a peculiar Bill and ought not to be taken as a precedent.

Mr. RENSHAW said that he could not agree with the views expressed by the hon. Member. His fear was that the amendment which had been introduced would cause great difficulty in many rural parts of the country. He believed there were many places where it would be perfectly impossible without great expense to bring a trained midwife to attend cases of labour. This ought to be considered, and he thought that if any words approaching those introduced in the Bill were to be maintained they ought to be modified in the direction of making it possible to put some charge upon a public rate so that hardship might not be involved. There was another point to which he wished to refer. The hon. Member for the Scotland Division of Liverpool (Mr. T P. O'Connor) had succeeded in getting on the Central Midwives Board a representative of the Royal British Nurses' Association. He congratulated him on his success and he wished to make an appeal for a representative of the Queen Victoria Jubilee Institute for Nurses. This institute was doing excellent work in every part of the country and he thought was entitled to a representative As the secretary informed him in a letter, the institute was engaged in supervising midwives all over the country and was constantly training them; it had on its roll at present between 400 and 500 midwives.

Mr. ERNEST FLOWER joined in this appeal.

Dr. THOMPSON said that there was no doubt whatever that the medical profession generally throughout the country was not at all satisfied with this Bill, but as medical men knew the great interest the hon. Member (Mr. Heywood Johnstone) had taken in the matter they had waived a great many of their objections, hoping that the discussion which had taken place might in the near future lead to an amending Bill. In Ireland they had almost as perfect a system of looking after lying-in women as was possible. They had well arranged dispensary districts and in each district a medical man with a midwife under him. The midwife could not act herself. The woman who was about to be confined got a line and went to the medical man and the latter sent a midwife to look after the patient. The medical man was in touch with the case and if the midwife saw anything wrong she sent for the medical man who came and did all he could for the patient He held that poor people had a right to this assistance. He was not quite sure that the Government were at all in favour of the very necess amendment which had been introduced during the report stage. E had heard the Under Secretary for Home Affairs say that it would be terrible thing to deprive poor people of the help of these handy wome in their time of trouble. Had the right hon. gentlemen ever heard antiseptic treatment? The very thing which they wished to gua these poor people from was dirt and he held that the very last thin that these handy women should do was to clean the house.

Mr. JESSE COLLINGS. But who is to pay for it?

Dr. THOMPSON said that if they established a proper system of di pensary districts as in Ireland there would be no trouble about t paying because the cost would be put upon the rates. He could testi to the danger that arose from the employment of these handy wom from their ignorance and carelessness and dirty habits. There we many defects in this Bill but still there were some good things in and he thought he might say this for the medical profession that th were not a money-grubbing profession. When they saw sufferi medical men never hesitated to relieve it, regardless of any consider tion of payment There was no profession which did more gratuito work. There was no medical man in the three kingdoms who wou not support him when he said that the amendment which had be introduced was absolutely necessary in the interests of the poor a his earnest hope was that the amendment would be retained.

Mr. PARKER SMITH said he did not think that the last speaker h said a word too much about the unselfish work of the medical pr fession. Everyone wished that poor women should in their time trouble get the very best skill, but how was it to be got? They h to look the facts in the face and they found that only a small propo tion of these women were able to afford the assistance of members the medical profession. Then it was admitted that an enormo amount of mischief was done by the ignorance and dirty habits of mi wives. This Bill was an endeavour to do as much as cou be done in the way of improving the state and the education midwives They must proceed gradually. He wished they could further than this Bill and he should be delighted if he thought it p sible to go further and insist upon higher qualifications, but he was opinion that any attempt to make the thing too stringent, to dema too elaborate qualifications, would simply be to make the thing impo sible and unworkable. He hoped that in the future they would be ab to make a further advance. In his opinion this Bill was a real st forward and would improve the quality of the ordinary midwife up a down the country. An hon. Member (Mr. Griffith Boscawen) had sa that the Bill was contrary to the tendency of the law. He should ha said that it was exactly in accordance with the law which w to restrict quacks and other unqualified professors of medicine. T law in other respects had not been to forbid unauthorised practi because it had been felt generally that that was perfectly impossibl It had been to register those who were qualified and to take every pr caution that those who were not qualified should not pretend that th were. The law could not stop them from practising altogether T law could not prevent him from taking advice from anyone in rega to his health or anything else, and from paying if he was so incline but the law could make sure that he did so knowing well that he w going to someone not recognised by the faculty. After this had be done everyone must be left to form his own judgment. He shou like to stop quacks very much but he was afraid that a Bill to th effect would not have very much chance of passing through th House He cordially supported the amendment which had been intr duced and he would be no party to any attempt to get it taken out the Bill in another place. He believed that during the interval seven years many of the women now in practice would be able acquire the knowledge and experience necessary for admission to t roll of midwives As a suggestion he thought provision might be ma for the admission to the roll of women of good character who we engaged in practice in 1910. What he thought about members of t medical profession was that sometimes they had been rather impra ticable in asking too much all at once and taking the line that becau they could not get all they wanted they would take nothing at all. the same time he believed that all through they had been actuated the highest motives

Sir WALTER FOSTER said that the present position was a somewh difficult one. They met a week ago with seven pages of amendments this Bill on the notice paper and with hardly any prospect apparent of the stage being completed at that sitting Then suddenly a almost unexpectedly they were all in harmony with referen to the Bill and the Bill passed rapidly through the report sta and was now before them for third reading. He hoped that t change made in the Bill would be maintained at all costs. La week they did not receive any explicit declaration from t Government of their adhesion to the new principle introduc into the Bill On the contrary, the Under Secretary for the Hom Department made a speech of considerable fervour defending t position of the unqualified practice of midwifery in rural district With that defence he had a considerable amount of sympathy. E thought, however, that the fears of the right hon. gentleman we exaggerated because under the Bill women in practice who were o good character would be able to go under the roll of midwives and so be able to carry on their calling without difficulty. The right hon. gentleman was very properly indignant with reference to the terms applied to some of these women. They had been called dirty but not in the ordinary sense. The term had been used in the purely scientific sense All that was wanted was that ignorant and untrained persons should not in the future be allowed to perform one of the most delicate and responsible functions which a woman could be called upon to perform for one of her sisters He wished to elicit from the right hon. gentleman a pledge that whatever changes might be made in the Bill at all events the words "habitually and for gain attend women in childbirth" should not be interfered with because the whole compromise, or so-called compromise, of last week hung upon the insertion of these words and the adoption of the date of Jan. 1st, 1910. They had given away a great deal by accepting this and he should be sorry if anything were done to interfere with the amendment. There was no thought of protecting the medical profession—he disavowed that entirely, but he did want that when the Bill became law care should be taken that at some day earlier than 1910, or even later, they should have security that every woman who performed these important functions was a properly instructed and informed person He could not say that he was satisfied with the constitution of the Central Midwives' Board. He did not think that the relation of county councils to the Bill was sufficiently defined and he did not think that the present form of it would work very freely. He should like to see the medical officer of health in every locality made more directly responsible for the supervision of these midwives. If they did something of that kind they should reinforce the very proper and just demand made generally that every county council should now have a medical officer of health. Altogether, he believed that this Bill was only part of a large measure of legislation which was needed by the country. He did not think that it was right to have been left in the hands of a private Member, and now that the Home Office had assumed to some extent some responsibility for the Bill he hoped that the Home Office would look after it very carefully and see it was not altered on the point he had named. In his view there was needed legislation for the exercise of supervision over all classes of nurses in the country.

Mr. BANBURY expressed general approval of the Bill.

Mr. T. P. O'CONNOR said that he entirely sympathised with the desire that the Jubilee Nurses should be represented at the Central Midwives Board, and in this connexion he pointed out that the Board was to a large extent a London Board, and he thought it would be well to have some representation on it of the provinces. He also suggested that the rules to be framed should be laid on the table of Parliament in order that, if necessary, Members should have an opportunity of discussing them. As to the compromise, he hoped that the Home Secretary would accept the verdict of this House. With regard to what the Home Secretary had said about himself, he would only ask the House to remember that when he voted against the proposal in the Grand Committee he was making the best battle he could to get some form of compromise. He admitted that difficulty might be encountered in the rural districts, but he would ask the House to bear in mind that they had begun a good work and he hoped they would continue it. He hoped that the promoters of the Bill would endeavour to assimilate the English to what prevailed in Ireland in this connexion. He thought it was somewhat discreditable to a rich country like England that it should lag behind Ireland.

Mr. COHEN accepted the Bill as a distinct advance.

Sir FRANCIS POWELL said that he had felt great regret that many of his medical friends had not regarded this legislation with more favour, but he was confident that when the Bill came into operation their views would undergo a change.

Mr. SCHWANN spoke in favour of the Bill.

Mr. JESSE COLLINGS said that he wished to reply to the appeal which had been made to the Government to pledge itself to take charge of the Bill in another place. It must be evident to the House that the Government could give no such pledge. From the beginning it had been perfectly understood that this Bill was not a Government Bill but was solutely in the hands of the House to deal with it as it thought best d that would be the position, he presumed, in another place. He ould vote for the third reading for two reasons. The Bill without e amendment which had been introduced was a thoroughly good Bill d a long step in the right direction—it prevented the term "midwife" ing used in a fictitious manner by those who were untrained and fit for the office. The second reason was that after the conciliatory d courteous manner in which the hon. Member (Mr. Heywood hnstone) had piloted the Bill through the House and the Grand mmittee it would be somewhat uncourteous to throw away his bours. The amendment which had been introduced would prevent y woman doctor from attending a childbirth.

Sir WALTER FOSTER: Women doctors practising in our large towns e all legally qualified for the practice of midwifery.

Mr. JESSE COLLINGS: But they would not be able to attend a child-rth unless they qualify under this Bill.

Sir WALTER FOSTER: They would be in exactly the same position as y medical man; they would be able to attend any case of midwifery.

Mr. JESSE COLLINGS said that in that case he did not know the meang of the words that no woman should attend a case of childbirth. It as a matter, however, that could be put right. He opposed the nendment because he believed it would inflict hardships upon the orer classes. He was glad to hear that the terms "Sairey Gamp" nd "dirty" and "ignorant" had been applied scientifically, but even applied he did not think that the terms should have been used. As class these women were honest and respectable people, and although ot trained scientifically they were trained by practice in the calling hey followed and at any rate they were an indispensable class. When he Irish dispensary system was recommended he would point out that his system should come first and the penalty afterwards. While proesting against this particular provision he offered no opposition to the hird reading of the Bill.

Mr. HEYWOOD JOHNSTONE said that he had no objection to the Queen ictoria Jubilee Institute for Nurses having a representative on the entral Midwives Board, all the more so because he believed that every urse trained under the rules of the institute was obliged to be a ualified and efficient midwife. He did not pretend that the ill was a perfect or final or complete settlement of what was n extremely difficult and important question. It might be, and e dared say it would be, but the beginning of that better state of hings which they were told prevailed in Ireland and which he hoped might in due course prevail in England when they had the experience and knowledge which would be gained by the Central Midwives Board created by the Bill. He had never regarded this as a final measure in any shape or form. He was only too glad to see the necessity for legislation recognised by the decision of the House. He had been invited to throw out some indication of what course might be pursued by the promoters of the Bill in regard to the amendment penalising unqualified practice in the other House. Bearing in mind that the insertion of these words was the result of a compromise he could only say for his part that he could neither directly nor indirectly in any way be a party to attempting to upset the compromise. He felt that in such a matter he ought not even to be approached on the subject either privately or publicly and he felt, too, that he ought to abstain from even an indication of his own opinion of what his own preference might be as to the retaining or the omitting of these words. There were grave and weighty arguments that might be used on both sides. On the one side it might be said, and truly said, that the penalising of unqualified practice was recommended by the Select Committee of 1893. It might be said also that it was urged with all the force of a strong medical opinion behind it, and he thought it might be said with even more force that it had often been said that much suffering and much mischief to the poor would still continue to result if they permitted people unqualified, ignorant, and untrained to carry on a practice so responsible and so full of possibilities and dangers. On the other hand, they had the strong argument that if not actually contrary it was certainly greatly in advance of the current of legislation dealing with these matters, that it was for the first time preventing persons from exercising a calling, which up to now from the days of the Pharaohs and even before had been a perfectly legitimate calling. They had also to bear in mind that it might be difficult or impossible to replace those who would be thrown out of practice. And there was besides the argument of the Under-Secretary that people of small means might be prevented from getting the assistance to which they had been accustomed. It had been suggested that this assistance might be provided out of the public funds. That was perhaps rather a delicate matter to touch upon, and he knew that many of those who belonged to the poorest class would shrink from availing themselves of public money; they had an honest and honourable feeling against it. He made these remarks with a view of pointing out to the House how many arguments might be fairly advanced upon both sides of this question, and he hoped that in doing so he had said nothing whatever to indicate any preference or judgment of his own on one side or the other. He was able to approach it from a perfectly impartial point of view because it had been his fate and duty to argue both sides of the question. The Bill left him with fragrant memories of zealous and kindly sympathy, of help tendered and given by many valued friends, by many unknown and he was afraid also unacknowledged, but not the less well-appreciated friends, and memories of useful criticism, of helpful suggestion, and of opposition in which if there was ever bitterness it had merged into respect, and respect had been succeeded by thorough goodwill and fellowship.

Mr. TOMLINSON, while speaking in favour of the Bill, hoped its provisions would be carefully scrutinised.

Lord HUGH CECIL suggested that the exact position of the Government with regard to the Bill should be explained.

Mr. JESSE COLLINGS said that he thought he had explained very clearly that this was not a Government Bill. From the beginning it had been regarded as a Bill fully in the possession of the House and one for which the Government was not responsible.

Lord HUGH CECIL: Then I understand that the Government does not consider itself to be in any degree bound by the compromise arrived at?

Mr. RITCHIE: I must make it quite clear. My position in regard to the matter is this. I prefer the Bill as it was originally but I very much prefer the Bill as it stands now to not having any Bill at all.

Sir WALTER FOSTER: The right hon. gentleman said that he would not oppose the Bill.

Mr. RITCHIE: I do not mean to oppose the Bill in any way, but when the hon. gentleman asked me that question I was speaking about the position of the Bill as it stood in the House and I said that I myself should not vote against the compromise. I certainly decline to be responsible for anything that the House of Lords may do. Over the House of Lords I have no control.

The Bill was then read a third time.

It now goes to the House of Lords.

BOOKS, ETC., RECEIVED.

AMERICAN CLIMATOLOGICAL ASSOCIATION, Philadelphia.

Transactions of the American Climatological Association for the Year 1901. Vol. xvii. Price not stated.

DEUTICKE, FRANZ, Leipzig and Vienna.

Des Kindes Ernährung, Ernährungsstörungen und Ernährungstherapie. Ein Handbuch für Aerzte von Prof. Ad. Czerny, Director, und Dr. A. Keller, Assistent, der Universitäts-Kinderklinik zu Breslau. Dritte und Vierte Abtheilungen. Price M4.50.

Lehrbuch der Klinischen Untersuchungs-methoden. Für Studierende und Praktische Aerzte. Von Prof. Dr. H. Sahli, Director der Medicinischen Universitätsklinik in Bern. Dritte umgearbeitete und ergänzte Auflage. Price M. 20.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

Anderton, J. E., M.R.C.S., L R.C.P. Edin., has been re-appointed Medical Officer of Health to the New Mills Urban District Council.

Blacker, G F., M.D. Lond., F.R.C S. Eng., F.R.C.P. Lond., has been appointed one of the Examiners in Midwifery to the Examining Board of the Royal College of Physicians of London and Royal College of Surgeons of England.

Blamey, James, M.R.C.S, L.S.A, has been appointed District Medical Officer for Perranarworthal by the Falmouth Board of Guardians.

Brown, George P., M.B., B.S. Univ. N.Z., has been appointed Senior House Surgeon at Dunedin Hospital, New Zealand.

Duncan, S. V., M R.C.S, L.R C.P. Lond., has been appointed District Medical Officer and Public Vaccinator for the District of Kookynie, Western Australia.

Easterbrook, C. C., M.A., M.D., M.R.C.P. Edin., has been appointed Medical Superintendent to the Ayr District Asylum, vice C. H. Skae, M D., resigned.

Garbutt, Richard H O., L.R.C.P., L R.C.S. Edin., has been appointed Certifying Factory Surgeon for the Tow Law and Stanhope Urban Districts and the Weardale Rural District, county Durham.

Gurdon, E. J., L.R.C.P. Edin., M.R C.S, has been appointed Officer of Health at Nannine, Western Australia.

Hawes, I. H. S., M B., B Sc. Durh, has been appointed Assistant House Surgeon at the Radcliffe Infirmary, Oxford.

Ick, T. E., M.B. Melb., has been appointed Public Vaccinator for the District of Broad Arrow, Western Australia.

McNaughton, J. G., M.D., M R.C.P. Edin, has been appointed Pathologist to the Clinical Hospital, Manchester.

O'Brien, Daniel P., F.R.C S I., has been appointed Visiting Medical Officer to the Meteor Park Orphanage, Stanwell, Rockhampton, Queensland.

Scott, Sack Noy, M R.C.S., L.R C P. Lond., has been reappointed Medical Officer of Health to the Plympton Rural District Council.

Stowe, William Reginald, M.R.C S, L R C.P. Lond, has been appointed Public Vaccinator for the District of Palmerston North, New Zealand.

Thurstan, E. Paget, M.D. Cantab, has been appointed *pro tem.* Acting District Medical Officer at Katanning, Western Australia.

Todd, C. E, L R.C.P Lond., M.R C.S. has been appointed Hon. Assistant Surgeon at the Adelaide Hospital, South Australia.

Twining, Vincent Wing, M.B., C M. Aberd., has been appointed Honorary Physician in Charge of the x ray Department at the Kingsbridge (Devon) Cottage Hospital.

Wigham, William Harper, M B. Durh., M R.C S., has been re-appointed Medical Officer of Health by the South Molton (Devon) Town Council.

Wilkinson, G. T., L R.C.P. Edin., L R C S.I., has been appointed Medical Officer of Health to Selby District Council.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Applecross District of the Parish of Applecross, Ross shire.—Medical Officer and Vaccinator.—Salary £95, with house

Ashanti Goldfields Corporation.—Medical Officer. Salary £500 per annum.

Beverley, East Riding Lunatic Asylum.—Assistant Medical Officer, unmarried. Salary £150, with board, lodging, and washing

Birkenhead Union Infirmary, Workhouse, and Sanitorium.—Assistant Medical Officer. Salary £120 per annum, with board, washing, and apartments

Blackburn County Borough.—Assistant Medical Officer of Health, unmarried. Honorarium of £50 per annum, with board and lodging.

Bristol City Lunatic Asylum.—Medical Assistant, unmarried. Salary £140 per annum, increasing to £160, with apartments, board, and washing.

Croydon Borough Hospital.—Resident Medical Officer. Salary £160 per annum, with board and residence.

Devonport Royal Albert Hospital.—Resident Medical Officer, unmarried. Salary £110 per annum, with board and lodgings

Fisherton Asylum, Salisbury.—Assistant Medical Officer, unmarri Salary £150 per annum, with board, lodging, and washing.

French Hospital and Dispensary, 172, Shaftesbury-avenue.—R dent Medical Officer, unmarried. Salary £80 a year, with board.

Glamorgan County Asylum, Bridgend.—Fifth Assistant Medi Officer, unmarried. Salary £170, with board, lodging, washing.

Hartlepools Hospital.—House Surgeon. Salary £100 per annu with board, washing, and lodging.

Hereford County and City Asylum.—Senior Assistant Med Officer, unmarried. Salary £150 per annum, with board, lodgi and washing. Also Junior Assistant Medical Officer. Salary £ per annum, with board, lodging, and washing.

Hospital for Consumption and Diseases of the Chest, Brompton Resident House Physicians for six months. Honorarium of £25,

Hospital for Women, Soho-square.—Registrar. Honorarium twen five guineas.

Hull Royal Infirmary.—Casualty House Surgeon for not less t six months. Salary £80, with board and lodging.

Ireland, Queen's Colleges.—Dunville Professorship of Physiology, also Professorship of Natural History.

Liverpool Infirmary for Children.—Assistant House Surgeon for six months. Salary £25, with board and lodging.

London County Asylum, Bexley, Kent.—Junior Assistant Medical Officer. Salary £150 per annum, with board, apartments, and washing.

London Hospital Medical College.—Assistant Demonstrator of Anatomy. Salary £90 a year.

London Hospital, Whitechapel, E.—Surgical Registrar. Salary £100 per annum. Also Assistant Surgeon.

Leicester Infirmary.—Assistant House Surgeon. Salary £80 per annum, with board, apartments, and washing.

National Hospital for the Paralysed and Epileptic (Albany Memorial), Queen-square, Bloomsbury.—Second Assistant House Physician. Salary £50 per annum, with board and residence, or £100 a year and board.

Newcastle-upon-Tyne, City Hospital for Infectious Diseases.—Resident Medical Officer. Salary £100 per annum, rising to £150, with board, lodging, &c.

Norfolk and Norwich Hospital.—Second Assistant House Surgeon for six months. Honorarium £20, with board, lodging, and washing.

Northampton General Infirmary.—Assistant House Surgeon, unmarried. Salary £75 per annum, with apartments, board, attendance, and washing.

Northampton: St. Andrew's Hospital for Mental Diseases.—Assistant Medical Officer for three months. Salary four guineas a week, with board, lodging, and washing.

Nottingham General Dispensary.—Assistant Resident Surgeon, unmarried Salary £160 per annum, with apartments, attendance, light, and fuel.

Parish of Fulham Infirmary, St. Dunstan's-road, Hammersmith, W.—Second Assistant Medical Officer for six months. Salary £80 per annum, with board, apartments, and washing.

Royal Edinburgh Asylum.—Assistant Physician.

Royal Eye Hospital, Southwark.—House Surgeon. Salary fifty guineas per annum, with board and lodging.

Salop Infirmary.—Assistant House Surgeon for six months. Salary at rate of £40 per annum, with board and apartments.

Sanitary Inspectors' Examination Board, 1, Adelaide-buildings, London bridge, E.C.—Examiner, who must be a Medical Officer of Health.

Somerset and Bath Asylum, Cotford, Taunton.—Assistant Medical Officer, unmarried. Salary £150 per annum, with apartments, board, &c.

Seamen's Hospital Society.—Surgeon at the Branch Hospital in the Royal Victoria and Albert Docks, E.

Throat Hospital, Golden square.—Senior House Surgeon (resident) and Junior House Surgeon (non-resident). Salary of the Senior £50 per annum, with board, lodging, and washing, and of the Junior £100 per annum, with lunch daily.

Walthamstow Urban District Council Isolation Hospital, Chingford.—Resident Medical Officer. Salary £120 per annum, with board and lodging.

Wangford Union.—Medical Officer. Salary at rate of £132 per annum, with fees

West Bromwich District Hospital.—Resident Junior House Surgeon. Salary £50 per annum, with board, lodging, and washing.

West Kent General Hospital, Maidstone.—House Surgeon, unmarried. Salary £120, with board and residence.

Wolverhampton General Hospital.—Assistant House Physician for six months Honorarium at rate of £75 per annum, with board, lodging, and washing.

Yorkshire College Leeds, Pathological Department.—Junior Demonstrator Salary £120.

Births, Marriages, and Deaths.

BIRTHS.

Le Fleming.—On June 11th, at Wimborne, Dorset, the wife of E. Kaye Le Fleming, B A, M.B, B C Cantab, M.R C.S., L R.C.P., of a son.

Power.—On June 10th, at Regent's Park-road, N.W, the wife of Capt. J. H. Power R A M C, of a son

Rygate.—On June 12th, the wife of H. B. Rygate, M.B. Durh, Fonnereau House, Ipswich, of a daughter.

DEATH.

Dickinson.—On June 11th, at Alassio, Italy, Edward Dickinson, M.R.C S Eng, formerly of Rugby, in his 89th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

"THE SEQUEL TO VACCINATION WITH GLYCERINATED CALF LYMPH"

THE *Redruth Times* of June 13th publishes a letter under the above title signed J. West, and dated from Stratford-on Avon, which contains a particularly silly and malignant falsehood concerning vaccination. The story which Mr. J. West tells is as follows:—

> "Amongst the most recent victims sacrificed at the altar of this modern Moloch is that of Job Williams, aged 29, who lived at 20, Kenmont-gardens College park, W., and was employed as a carman by Messrs. Warner and Company, Flora Wharf, Harrow road by whom he was sent with a load of building material to the new isolation hospital in course of construction at Dartford. Before being permitted to enter the premises re-vaccination was sought to be insisted upon, but for four hours Williams resisted the demand and finally gained his point. On a second journey about a week later, however, he felt that his situation would be jeopardised by a further refusal and so he submitted to the operation. A 'terrible' arm resulted, the inflammation appeared to strike inward, and in 15 days the poor fellow died. He had not previously suffered a day's illness but was a robust man and he leaves a widow and two young children."

This awful story is duly prefaced with remarks about "preposterous adulteration" and "consignment to limbo" and concludes with a string of such phrases as "mischievous vaccination fetish," "despicable tyranny," and "hateful delusion"; so that when we read Mr. J. West's effusion we knew that it emanated from the usual violent muddle-headed opponent to medical science. But as he gave exact details we did him the honour without believing him, to make inquiry into his facts. So we addressed a letter to Messrs. Warner and Co., Flora Wharf, Harrow road, begging particulars of the tragedy. A reply duly reached us from West's Stourbridge Brick Co., Ltd., whose depôt is the Flora Wharf, Harrow road, W., and who sign as "late Warner and Co." West's Stourbridge Brick Co. say that no such man has ever been in their employ as Job Williams and that, as far as they know, there is no truth whatever in the story. In these circumstances Mr. J. West owes apologies all round for circulating a silly circumstantial lie. We are not sure if he sent the letter to the *Redruth Times*, for it is headed "To the Editor of the *Cornubian*," but the Editor of the *Redruth Times* has the right to be sore at the mendacity of the story to which he has given circulation. The Editor of the *Cornubian* ought to be yet more aggrieved; while the explicit insinuation that the proprietors of the Flora Wharf have driven an employé to death may well be resented by West's Stourbridge Brick Company. We do not suppose that any of these people will think Mr. J. West worth a thought and although we have exposed his inaccuracy we have not stopped the dissemination of the yarn. The tragedy of Job Williams will yet be narrated from platforms and quoted in provincial newspapers. Job Williams will leave, in addition to the widow, aged parents to mourn their loss. He will die of all sorts of complications and the two orphans will expand into a large family of bereaved infants. But though we know that it is most unlikely that we shall be able to overtake Mr. J. West's lie we still think it right that it should be hall-marked as such.

HOMES FOR EPILEPTICS

To the Editors of THE LANCET.

SIRS,—I shall be very much obliged if any of your readers could tell me where there is a home which would take in an epileptic girl of about 25 years of age, strong and otherwise healthy except for a slight mental deficiency, willing, and able to work. She has £350, which is bringing her 4½ per cent., and this would be paid to the institution. She is of the small-farmer class of life.

I am, Sirs, yours faithfully,

W. G. WILLOUGHBY,

Medical Officer of Health of Eastbourne.

Eastbourne, June 17th, 1902.

THE ABORTION MONGER.

WE have frequently referred to the infamous advertisements of abortion-mongers which appear from time to time in the daily or weekly press. Their trend was quite obvious although veiled in ambiguous language. A correspondent, however, has sent us a leaflet which he says was left at one of his surgeries. This leaflet sets forth the talents and successes of an abortionist called Madame J. Jacobsen whose only address is 22, Mather-street, Newcastle-on-Tyne. The bill contains the usual lies about obstructions and irregularities and further states that "it is a subject too which for various reasons the medical world give very little attention to, hence the frequency of their failure to give relief when relief is most essentially needed." Madame Jacobsen sells a female mixture which "is warranted to be superior to all other female medicines, inasmuch as it will positively restore irregularity." It seems, however, to have struck Madame Jacobsen that the restoration of irregularity was a somewhat questionable boon, for she also sells special female pills which "never fail to give relief." Madame Jacobsen also states that the "utmost secrecy may be strictly relied upon." She, however, gives a variety of testimonials from which we extract the following. It will be seen that, by the writers' statements, it is no question of simple amenorrhœa.

"Manors Station Arches, City road, Newcastle.

DEAR MRS. JACOBSEN,—Please forward by return of post to my address one box of your Special pills, for bringing about all that is required. I had a box of them before and found them just the thing.

Yours truly,

Mrs. B."

"Consett.

DEAR MRS. JACOBSEN,—Will you kindly forward me another bottle of your Strongest Mixture, also a box of your Special Pills, for which I enclose Postal order trusting you will send it as soon as possible. It is four weeks over the time, so you will know what to send for me, and I beg of you to do your best to put me right. I think you will understand my case, as you have cured me three times before.

I am, yours sincerely,

Mrs. L. N."

Mrs. B. N., it will be observed, is an old hand and takes matters in time. Others are not so provident.

"Hector-street, Gateshead-on-Tyne.

DEAR MRS. JACOBSEN,—I must thank you for extra care bestowed upon my case. I became all right yesterday after taking only half of the second bottle of Mixture. I consider your medicines to be the best in the world for removing obstructions. My case was a stubborn one of 16 weeks standing but with your good advice I succeeded, for which I am truly grateful. I shall always recommend you.

I am, dear Mrs. Jacobsen, yours truly,

MRS. N."

These unblushing testimonials conclusively show that abortion is the object of the persons who take the pills and medicine. Whether their effects are aided by other means or not we cannot say but we should not be surprised if this were the meaning of the phrase "extra care" employed by "Mrs. N." We are forwarding a copy of the current number of THE LANCET to the Chief Constable of Newcastle who will perhaps pay a visit to Madame Jacobsen's "only address."

CERTIFICATES FOR INSURANCE SOCIETIES

To the Editors of THE LANCET.

SIRS,—May I ask for a reply in THE LANCET to the following? I am often asked, as well as other medical men I presume, to fill in certificates of death for life assurance societies on a special form, wherein one is requested to state certain facts as to the cause of death and duration of illness beyond what is demanded by the usual death certificate. I have been in the habit of declining to fill in these papers, referring the companies to the registrar for a copy of my death certificate, as it seems to me one might, by the further information supplied, inadvertently lead to wrong inferences being drawn as to the causes of death and so possibly bring about legal difficulties. 2. If filled in what range of fees should be charged?

I am, Sirs, yours faithfully,

X.

*** Most life offices require the representatives of the deceased to obtain a certificate from the medical attendant in the form desired by the particular office. This form varies according to the office. The medical man cannot be compelled to sign it but we have never heard of a refusal. The fee charged should be according to the usual scale of fees for attendance.—ED. L.

MOTOR CARS FOR MEDICAL MEN

To the Editors of THE LANCET.

SIRS,—In the autumn of 1900 I had the pleasure of writing you a short account of the experiences I had with a Benz motor car which I bought in May of that year (*vide* THE LANCET, Oct. 6th, 1900, p. 1045). Perhaps now I can write with greater authority on the subject, as I have continued to use the car (except when *hors de combat*, which I regret to have to say has been rather frequent of late) until the present time. To take matters *in extenso*:

The carriage.—After two and a half years any carriage, I presume, would wear and as I have not had mine repaired as yet the appearance is not prepossessing and the frame rattles and is worn and loose; the paint, too, is conspicuous by its absence.

The tyres.—The district in which I use my car is hilly and the roads are the reverse of good, so you will not be astonished to hear that I am using my third set of tyres on the driving or back wheels. On both occasions I have bought the same tyres as supplied with the car, "Connolly Ideal," solid wired on to the rims. I understand and believe they are the best, especially for constant use such as that of a man in practice. With rough wear I find a set lasts about 14 months. I believe I paid £12 for the four tyres, or £7 for the tyres on the driving-wheels.

The transmission gear.—Mine being an early type of Benz the power is conveyed by two belts to the counter-shaft, the belts running on loose pulleys on the counter-shaft and being shifted on to keyed pulleys by a fork. As you may remember, I mentioned in my previous letter that in one of my longer runs the second-speed loose pulley, through improper lubrication, seized and had to be rebushed. Apparently in bushing the journal cracked; any way, since then I have had to have a fresh pulley. The keys that fix the sprockets to the counter-shafts have also worn and once when I was driving one fell out and left me in a hole, the countershaft revolving and not driving the sprockets. Recently the sleeve on the right of the counter-shaft, over which the second-speed loose pulley revolves, broke away from the teeth of the compensation gear to which it is keyed, the result being once more the revolution of the counter-shaft without driving the sprockets and a journey home behind the car which was not as pleasant as one seated in it. A new sleeve which took three days to get soon remedied matters. The forks that shift the belts easily wear and then, while driving on one belt, the other is apt to slip off the loose pulley and pull the car up. Steel tubing placed round the sides of the forks prevents this wear and can always easily be renewed. The only other matter that requires attention on the transmission gear is the ball bearings that fix it to the car. I should always advise carrying a loose collar for the ball-bearing. On two occasions I have had a collar break and the balls fall out.

The engine.—The water-joints on the cylinder, especially the one at the back, have occasionally to be renewed—a not pleasant or easy task to do. A leakage can always be told by the presence of water in the cylinder. I make a rule of opening the cylinder-cock every morning and if on pulling the fly-wheel round much water escapes I know the water-joints want seeing to.

The valves.—The valves want frequent grinding, otherwise there is a great loss of power. The advantage in the old Benz is that both the inlet and exhaust valves have vertical spindles, horizontal ones are apt to wear more on one side than the other and so to stick. The exhaust valve is lifted up by a quadrangular arrangement worked by a cam. The teeth on the cam are of fibre. On one occasion while in Hampshire two of the teeth broke off and if I had not luckily come across the possessor of another Benz who allowed me the loan of his cam I should once more have had to proceed home by other means than the car. My advice is, always carry a spare cam. The arrangement in the new Benz for working the exhaust is better The rods on mine wore so much oval that I had to get a fresh set, though I believe mine could have been rebushed.

The cylinder.—This is, I presume, the great objection to the Benz, being horizontal, the advantage claimed for this type being, however, greater ease in lubrication and consequently less wear. Undoubtedly n all horizontal types the cylinder is apt to wear oval, and though I have had new piston rings fitted recently by Hewetson the power is not as good as before and I have no doubt that there has been bed wear and that it is a little oval

The bearings —I have had to have fresh brasses fitted on to the crank and the side bearings are now greatly worn, and as they allow too much play will doubtlessly soon have to be replaced by new ones. The brasses on the crank when they wear oval can be filed and so tightened.

I use Wellington belting and find that it lasts well and gives little trouble. The new Benz, I believe, has an arrangement to prevent the belts getting wet—a cause of slipping. On my car I have fixed a piece of oilcloth in front which generally keeps them dry. The teeth on the steering rods have worn quite sharp and therefore the rods have recently had to be replaced. The wheels run on ball bearings and in the time I have had the car the spokes have not given any trouble. Of course, the bearings require periodically seeing to and the worn balls to be removed and fresh ones inserted. The chains are Brampton's and of course require occasional picking up. I am now using my third set.

Conclusions —At the end of my last communication I fear my conclusions were rather gloomy. Are they better now? I have had much pleasure out of the motor. I have had many worries Occasionally on the road to an urgent case I have had to get out and walk. More than once have I been obliged to engage a cab when the motor was undergoing repairs. And then the question of expense My bill from Hewetson for this year only for repairs is £30 and this does not include £12 spent on tyres. Such being the case I hesitate to recommend my professional brethren to embark in one. I give them the facts and leave it to them to draw their own conclusions both as regards the Benz and other cars. I may conclude by saying that I am seriously thinking of trying another myself. I am, Sirs, yours faithfully,

CHARLES T. W. HIRSCH, M.R.C.S. Eng , L R C P Lond., L S A ,
Public Vaccinator and Police Surgeon, Woolwich,
late District Medical Officer, Colonial Medical Service, Fiji.
Woolwich, June 14th, 1902.

THE "Y" FUND.

SURGEON-GENERAL H. S. MUIR begs thankfully to acknowledge additional donations towards the above Fund from The Marchioness of Ripon, Lady Mitchell Banks (who sent kind donations from Lady Tate, "Two Friends," Mr and Mrs. Wilkinson, Mrs. Illingworth, Mrs. Pearson, Mrs Whitewell, Mrs. Harris, Mrs. Blood, Mrs Fleetwood, Mr. and Miss Hakes, Mrs. MacFee Campbell, Mrs. F. Johnston, Mrs. Barr, Mrs. Wright, Mrs. McAllister, Miss Carter, Mrs. Thirlwall Thomas, Miss Grünbaum, Mrs. Burton, Mrs. Withers, Miss Binger, Mrs. Dalzell, Mrs. Stevenson, Mrs. Caton, Mrs. G. Walker, Mrs. H. Nicholls, Miss Abram, Mrs. Cunliffe, Mrs. Gee, Mrs. Westby, Mrs. Robinson, Mrs. Mahler, Mrs Rankin, Mrs. Graves, Mrs. Brannigan, Mrs. Horniblow, Mrs Riggs, Mrs. Bur T. A. W., C. N. W , M. G. W., Dr. W. Edgecombe, Dr. T. R Dr. J. M. Hunt, and Mr. Murray), Captain and Mrs. S (with kind donations from Mr. E. Pandorf, Mrs. Drab Mrs. Carr Shaw, and Mrs. Blindstone), Dr. and Mrs. kind donations from Dr. W. B. Stokes, Dr. A. R. H Beauchamp, and Mr. Walter Tyrrell), Surgeon Gen Wilson, K.C.M G , A.M.S., Surgeon-Lieutenant-Colonel nsman, C.M.G., A.M.S. (retired), and the following officers of the Royal Army Medical Corps: Lieutenant-Colonel H. W. Murray, Majors W. H. Pinches, and A. Hickman Morgan, D.S.O.; Captains W. Mould and G. A. T. Bray; and Lieutenants T. O. Lauder a E. McDonnell. The fund now amounts to £305. It may be explain that this is in response to an appeal made privately to membe of the profession for benevolent aid in a distressing case whic has been described in a letter sent to a limited number medical men (who would help the cause by kindly "handin on" to *confrères*). Should any reader of THE LANCET desire furth particulars with a view to expressing *practical sympathy*, a copy the letter will be forwarded on application to Surgeon-General Mui 26, Kensington gardens-terrace, Hyde Park, London, W.

A PLACE OF RESIDENCE.

To the Editors of THE LANCET.

SIRS,—In reply to "P. P.'s" query in THE LANCET of June 14t p. 1743, regarding a place of residence the Isle of Man would sat factorily fulfil the requirements. An illustrated guide-book with chapter on the climate may be obtained free of charge and post fr on applying to Mr W. Keig, secretary of the Board of Advertisin Douglas, Isle of Man. I am, Sirs, yours faithfully,

June 16th, 1902. J. H. B.

THE LAW FUND.

TRUSTEES. THE PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS LONDON, THE PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND, AND THE MASTER OF THE SOCIETY OF APOTHECARIES OF LONDON.

WANTED—A DIAGNOSIS.

To the Editors of THE LANCET.

SIRS,—Can any of your readers help me with diagnosis in the followi cases? One is a man aged 80 years and the other is a man aged 60 yea They are practically identical; both are active, healthy, careful me and both are of a gouty habit. So long as they are up they feel nothin but no sooner do they get to sleep than they are awakened by pains both hands and forearms. The hands feel as if they were swollen b nothing is apparent to others except that they are perhaps a little re certainly not blue or pallid. Posture in bed has no effect, and the on thing that gives any relief—and this is only partial—is to raise t hands above the head. It has existed for a year or two. With ea every likely remedy has been tried; nothing has any effect and th are gradually suffering more and more. Any suggestions as to cau would be valued. I am, Sirs, yours faithfully,

June 17th. X.

PROPOSED MEMORIAL TO THE LATE SURGEON-GENERAL W. NASH, A.M.S.

THE following additional subscriptions to the fund have been received:—Surgeon General J. O'Nial, C.B., £1; Lieutenant-Colonel A. B Cottell, £1 1s.; Captain T. O. Lauder, 10s.; previously acknowledged, £101 11s. 6*d*. Total, £104 2*s*. 6*d*. The committee desires to intending subscribers that the Fund will be closed on

RYGATE —On ext.
Fonnereau H

◆

—"Filatow's spots" are the same as "Koplik's spots" ts which have been found in the earliest stages of measles

DICKINSON garded as pathognomonic symptoms of that fever. A short this eruption will be found in THE LANCET of Feb. 2nd, 1901, p 347. The *Journal of Physiology* and *Brain* might be consulted for Dr. Head's paper. We have not the exact reference, we regret to say.

New Jersey, Lübeck, Aix-la-Chapelle, Hamburg, and a number of other places; the one at Aix was particularly interesting as it was brought about by cases in the house of a dairyman, which were called by the medical attendant "gastric fever" and were not notified to the public authority and therefore no precautions were ordered; the excremental matters of the patients were thrown on a dung-heap from which they soon soaked into the well, the water of which was used to wash the milk-cans. The outbreak ceased on disuse of the well-water and connexion of the dairy with the town water-supply. The circumstances of this outbreak were very similar to those of the Marylebone outbreak in 1873 (Deutsche Vierteljahrschrift für Öffentliche Gesundheitspflege, vol. xxxii.).

III. Dr. J. Adolf Kraemer gives a very interesting account of an outbreak in an infantry regiment. Tired out by a long march in July and very thirsty the soldiers came to a place where they were given plenty of milk. The result was that 142 of them fell ill about the end of the second or beginning of the third week after drinking the milk; of these "81 had true typhus abdominalis, 31 febris typhosa sive gastrica, and 30 had indefinable symptoms." It appeared that in the house whence the milk was obtained there was a person suffering from typhoid fever and this case was at first regarded as the source of the outbreak, but it was found afterwards that it was contracted at about the same time as the cases among the soldiers and the poison appears to have been derived from a case which occurred in the previous year (Zeitschrift für Klinische Medicine)

THE

SURGICAL TREATMENT OF OBSTRUCTION IN THE COMMON BILE-DUCT BY CONCRETIONS,

WITH ESPECIAL REFERENCE TO THE OPERATION OF CHOLEDOCHOTOMY AS MODIFIED BY THE AUTHOR, ILLUSTRATED BY 60 CASES.[1]

BY A. W. MAYO ROBSON, F.R.C.S. ENG.,
SENIOR SURGEON TO THE GENERAL INFIRMARY AT LEEDS; EMERITUS PROFESSOR OF SURGERY IN THE YORKSHIRE COLLEGE OF THE VICTORIA UNIVERSITY.

WHEN once gall-stones have reached the common duct, their attempted dislodgment by purely medical means is with few exceptions disappointing in the extreme and the unfortunate patients are condemned to a lingering and painful illness, usually ending in death, unless the obstruction can be removed by surgical intervention. Seeing that it is only 11 years since Courvoisier first removed a gall-stone from the common duct by direct incision the progress in this branch of surgery must be very pronounced when we can safely affirm that there is no portion of the gall-bladder—cystic, common, or primary division of the hepatic ducts—which cannot under ordinary circumstances be reached for the removal of concretions and that with great probability of success.

No surgeon should attempt the removal of gall-stones unless he is prepared for any of the various operations on the biliary passages, as it is almost impossible to say beforehand what may be required until the ducts have been explored by the fingers and the condition of the parts ascertained, and no operation should, as a rule, be concluded until it is clearly made out that the ducts, including the hepatic and common ducts, are quite free from concretions, otherwise disappointment and dissatisfaction are certain to follow.

Arguing from some hundreds of cases of cholelithiasis on which I have operated I find that the common bile-duct has to be attacked in one out of every five or six cases. In a few cases concretions may be manipulated backwards into the gall-bladder and thence extracted by scoop or forceps, but this can only be done when the cystic duct is dilated I have been able to clear the ducts in this way on 10 occasions. Occasionally a small stone may be pressed into the duodenum, but this is exceptional and inadvisable, as it may be pushed into the diverticulum of Vater and so be missed and the whole operation rendered futile. In patients too old or too ill to bear choledochotomy a rapid cholecystotomy may be performed so as to relieve the jaundice and allow solvent injections to be employed, but my experience of this treatment has not been so favourable as to make me very hopeful of accomplishing the solution or the diminution to the passing point of the concretion deliberately left behind and a subsequent operation is usually necessary.

Crushing concretions by means of pressure by the finger and thumb through the duct walls is a method which I formerly employed in over 30 cases with considerable success and without fatality, but it is only available for soft concretions, and fragments are apt to be left and then to produce further trouble. I have not once adopted this method during the past two years unless I could at the same time remove the fragments.

Cholecystenterostomy or short-circuiting the obstruction should never be performed for gall-stones as it leaves the cause untouched and the small opening is apt to contract and to lead to speedy recurrence of the symptoms. This has actually occurred in my own practice and in that of other surgeons. Out of nearly 30 cholecystenterostomies that I have performed I have only done it on 10 occasions for gall-stones and not once during the past two years.

If the patient be too ill for choledochotomy the gall-bladder can be very rapidly united to the colon with very little disturbance of adhesions, and this as a means of giving relief answers quite as well as the more difficult operation of uniting the gall bladder and duodenum; this operation is, however, only applicable when the gall-bladder is dilated, which is unusual in cholelithiasis.

The operation of uniting a dilated duct to the intestine or draining a dilated duct on to the surface may be occasionally called for and I have twice done the former and once the latter operation and in all the cases recovery followed.

Reaching the common duct through the opened duodenum, a modification of choledochotomy, seemed to me when it was first suggested by Dr McBurney an easy and ideal operation and at that time it was easier than ordinary choledochotomy, but I feel sure that there is a greater danger of sepsis by this method owing to the necessary enterotomy, and since I have adopted my modification of choledochotomy I have not repeated the operation through the duodenum, since I am quite clear that it is not only more difficult and more dangerous, but that it does not afford so great a facility in clearing the whole of the ducts of concretions. I have performed it 11 times with three fatalities, which compares unfavourably with the ordinary operation of choledochotomy

Lastly, and most important, we come to the ideal operation for the removal of stones from the common duct, choledochotomy, which, after experience of all other methods in vogue for the removal of gall-stones from the common duct, I have come to the conclusion is the only one to be relied upon and as an operation is therefore worthy of special study. Moreover, as the result of my experience in 60 cases I have been able to modify the operation in such a way that what was formerly a most difficult procedure, involving prolonged manipulation, special appliances, and at least two assistants, and only to be undertaken after all other means had failed, is now a comparatively simple operation in the greater number of cases, only requiring the help of one assistant and not requiring the use of any special apparatus. By this method the time involved in the operation is reduced considerably, and where adhesions do not give unusual trouble it is easy to complete the work in from 30 to 40 minutes, which not only means a saving of time and fatigue to the operator but a considerable saving of shock to the patient. I always employ a firm sandbag under the back opposite to the liver, which not only pushes the spine and with it the common duct forward so that it is several inches nearer the surface, but acts like the Trendelenburg position in pelvic surgery by letting the viscera fall away from the field of operation. I then make a vertical incision over the middle of the right rectus, the fibres of which are separated by the finger, which I find to be the most expeditious and the most effective method of exposing the gall-bladder and bile-ducts; but when it is necessary to open either the common duct or the deeper part of the cystic duct, instead of prolonging the incision downwards, as was formerly done, I now carry it upwards in the interval between the ensiform cartilage and the right costal margin as high as possible, thus exposing the upper surface of the liver very freely. It will now be found that by lifting the lower border

---

[1] A paper read before the Royal Medical and Chirurgical Society on March 25th, 1902.

Retired M.R.C.S.—Almost invariably the best advice is to recommend the patient to be satisfied with her lot. The only possible procedure is to improve the general nutrition and thus to fatten the patient. We certainly do not recommend local massage, but perhaps our correspondent means general massage with inunction of oil which possibly would be of service. The perils of quackery should be insisted upon

Bodeul.—There is no way for the unqualified son to keep the practice up in his deceased father's name. A medical man may be found to work the practice on a salary with the understanding that he will retire when the son has passed his final examination, but that medical man cannot practise under the name and style of the dead practitioner.

Mr. R. H. Powers.—Lists of sanatoriums for the outdoor treatment of pulmonary tuberculosis were given in THE LANCET of Sept. 9th (p. 724) and 23rd (p. 851), 1899 These are no longer complete. "Burdett's Hospitals and Charities, 1902," p. 707, might also be consulted.

ERRATA.—In paragraph No 12 of THE LANCET Commission on Glycerinated Calf Vaccine Lymphs, which appeared at page 1624 of THE LANCET of June 7th, the words "The Rebman Publishing Company" should be "Rebman, Limited." In line 2, column 2 of the same page No. 243 should be No. 343. In the paper by Professor F. O. Madden, published in THE LANCET of May 31st, p. 1533, line 2, column 2, should read, "remained fairly satisfactory for six days after the operation," instead of as printed, "six hours."

During the week marked copies of the following newspapers have been received:—*Lincolnshire Echo, Torquay Directory, Burnley Gazette, Northern Times (Golspie), Reading Mercury, Herts Advertiser, Times of India, Aberdeen Free Press, Lancashire Post, Plymouth Morning News, Western Mercury, Yorkshire Post, Pioneer Mail, Devon and Exeter Express, Burnley Express, Scotsman, Ipswich Times, Dublin Evening Telegraph, Southampton Echo, Belfast News, Lancaster Guardian, Bradford Observer, Sheffield Daily Telegraph, Municipal Reformer, Echo, Daily Express, Standard, Bristol Mercury, Windsor and Eton Express, Globe, Westminster Gazette, Sunday Times, Derbyshire Times, &c.*

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (23rd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.) West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.).

TUESDAY (24th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Royal Ear (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.).

WEDNESDAY (25th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.)

THURSDAY (26th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.) St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

FRIDAY (27th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square, (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.)

SATURDAY (28th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (23rd).—ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (20, Hanover-square, W.).—7 P.M. Council. 8 P.M. Communications:—Mr. A. Underwood: (1) Dental Irritation in a Case of Malignant Disease; (2) A Case of Pulp-stones; (3) A Case of Buried Wisdom Tooth discovered by X Rays and Removed. Paper:—Dr. S. Wallace: Some Effects of the Refinement of Food. The President: Valedictory Address.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (23rd).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. J. H. M. MacLeod: Clinique. (Skin.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Dunn: Ocular Therapeutics.

TUESDAY (24th).—POST-GRADUATE CLINICAL DEMONSTRATION (Westminster Hospital).—4.30 P.M. Dr. Murrell: Cirrhosis of the Liver.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury).—3.30 P.M. Dr. Tooth: Cerebral Infantile Palsies.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Bidwell: The Preparation and Application of Sutures and Ligatures.

WEDNESDAY (25th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Cole: Medico-legal Relation of Insanity.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only. AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

The Cavendish Lecture

ON

INFLAMMATION OF THE VERMIFORM APPENDIX.

Delivered before the West London Medico-Chirurgical Society at the Town Hall, Hammersmith, on June 20th, 1902,

BY SIR FREDERICK TREVES, K.C.V.O., C.B., F.R.C.S. ENG.,

SURGEON TO H.M. THE KING; CONSULTING SURGEON TO THE LONDON HOSPITAL.

MR. CHAIRMAN AND GENTLEMEN,—The subject is the not perfectly novel one of appendicitis, the reason being that there are certain points in connexion with this trouble which I think are still open to discussion. I should imagine that there has scarcely been anything more remarkable in the way of medicine at the close of the nineteenth century than the sudden appearance of the disease now known as appendicitis. If we remember that this is proportionally the very commonest acute malady met with in the abdomen excepting possibly the complications of hernia it is really astounding that 20 years ago this affection was absolutely unknown. It was not until the year 1886 that the very name itself had any existence. It was, as a matter of fact, by Fritz in 1866 that the name was first used, and it is particularly curious that he used it in a sense totally apart from the sense in which it is used at the present day One knows that the academical-minded have a great objection to this uncouth term "appendicitis"; it lacks precision, but it has found its place in the clumsy nomenclature of medicine and has been accepted by the public with an extraordinary amount of generosity. Of course, I need not say that under no circumstances is appendicitis to be regarded as a new disease It is probable that even the cave man with his rudimentary methods of eating suffered occasionally from appendicitis. The disease is not new but newly discovered; it has been hidden for centuries under a lot of vague clinical facts and medical verbiage. In old records we hear about appendicitis as gastric catarrh, gastric seizure, cramp of the bowels, iliac phlegmon, and many other terms. Moreover, a large number of examples of peritonitis were no doubt examples of appendicitis. In 1887 a certain elaborate treatise on peritonitis included no less than 28 entirely different forms of that particular affection. There are a few earlier reports of the trouble and in those earlier reports the appendix was blamed as being the cause of the disturbance. But all these earlier reports were like the voice of men crying in the wilderness, no sort of heed was paid to them although there were two authors who accused appendicitis of being the cause of what was then known as iliac phlegmon.

The point that should be first insisted upon in connexion with this malady is this it is a pure peritonitis There is no consideration about it which is apart from peritonitis. Until the peritoneum is involved there is no malady An acute attack of appendicitis is an attack of peritonitis. It is very desirable, therefore, that in speaking of this affection we speak of a definite form of peritonitis, and the features and complications and possibilities of the malady and the treatment to a certain extent are simply those of peritonitis. No progress will be made, I think, until a proper estimate of this malady is realised and all terms about the twisting and turning of the appendix are thrown aside. Then it will be understood that the trouble is nothing but a form of peritonitis. That leads me to say one word about the disease originally in the appendix. Fritz used the term to describe a malady that had no symptoms; he described it to indicate those changes in the appendix which preceded the implication of the peritoneum and which clinically may have no kind of existence. In connexion with that point I should like to emphasise these three solitary facts. The first is this that quite extensive changes may take place in the appendix without the production of a single solitary symptom. The appendix may be almost obliterated without the production of a single symptom of appendicitis, its mucous membrane can be entirely destroyed, and it can become stenosed or shrunken without the production of a single symptom. I am reminded of a case in which I was doing the ordinary operation of ovariotomy and I came across an appendix showing the grossest changes. In this case neither the patient nor the medical attendant had any suspicion of trouble in the appendix, for this woman never had any symptoms of appendicitis. The second fact is this. An attack of appendicitis, as we know it, may be preceded by a number of minor disturbances or minor seizures for which we have no name but which may be included under the title "appendicular colic." But this term is actually wrong Colic, I imagine, means pain in the intestinal tube due to disorderly muscular action and there is no muscle in the appendix capable of producing the phenomenon of colic. A patient gets an attack of pain in the abdomen with a feeling of nausea and this lasts for perhaps two or three hours and then the whole thing is gone, but these troubles do not come under the head of appendicitis and probably do not concern the actual peritoneum. Thirdly, we must take a little more heed of a condition that should be called chronic appendicitis as seen in patients who have an abiding trouble in the right iliac fossa but never an attack of appendicitis. These attacks of chronic appendicitis are common enough. Some men and women are never free from some sense of discomfort in the abdomen—a gnawing pain, a burning pain, a griping pain, a feeling that there is something coming away there, a desire to support the back. People often walk across the room with the body bent and the hand pressed on the abdomen. These symptoms come under the proper heading of chronic appendicitis and should be more fully recognised than they are now To these three remarks I should like to add another as to the ridiculous classification of appendicitis. Every monograph on the subject begins with a ridiculous list of forms of appendicitis—the gastric form and so on—and if you discuss a case with a medical man he often says: "Do you think this is catarrhal or suppurative, or what is it?" This same elaborate classification has a place in the history of all maladies There was a time, for instance, when there were about 15 or 20 different forms of pleurisy and these all came down to one thing How many forms of synovitis were there 20 years ago? How many forms are there now? Inflammation of the appendix, catarrh of the appendix—what does it lead to? Ulceration, stricture, perforation, gangrene. There is nothing to be gained by this ridiculous classification. Appendicitis is an inflammatory trouble due to certain micro-organisms and it begins as a catarrh, excepting cases of actual torsion. I do not propose to say anything in detail as to the causes, or reputed causes, of this malady We know it is most common in young people, 80 per cent. of the cases coming under the age of 30 years and, curiously enough, 73 per cent. occurring in males.

I should like to draw attention to certain factors in the cause of appendicitis which I think have a good deal to do with the treatment of the disease. The first factor is the extraordinary effect of a tropical or sub-tropical climate. I have often said that, although my practice is in London, a large proportion—I will not say the majority—of my patients come from tropical countries, not necessarily hot countries but countries in which intestinal trouble is inevitable, such as India, the Straits Settlements, China, South Africa, and other plac[illegible] to them. It is obvious how these cases are so freque[illegible] persons with a disturbed appendix go to a country in which intestinal troubles are common and being more liable to the disease they contract it. I think therefore that no person should be allowed to go to a tropical country if he is a suspected subject of trouble in the appendix. It is very noteworthy how persons who have had a little suspicion of this malady in themselves will come to an acute termination of it after having gone to reside in a tropical or sub-tropical climate. Another curious point is the frequent coincidence in the female subject of an attack of appendicitis with the menstrual period. It cannot be an accident, because in one particular case that I had the attack occurred on the fourth or fifth day and never varied from that. One might say that out of nine or 10 attacks in females perhaps as many as four or five will be associated with the menstrual period. Of course, that is explained by the circumstance that the two organs concerned are closely allied and that they certainly can mutually disturb one another. I have actually seen a cystic ovary in a child, aged 10 years, and attached to that cystic ovary a diseased appendix; I was unable to arrive at the conclusion that the appendix was the cause of the cystic condition of the ovary. Anyhow, these two organs are close together, and I need not remind you of the fact, which has been well demonstrated, that they have the same lymphatic arrangement. The association of these two maladies is very common and I think it should be a matter of routine in every case in which the appendix is removed in the female subject that the right ovary should be inspected, because the cases in which this organ has been so diseased as to need removal are very striking. One must remember that fact in the causation of appendicitis because we cannot get away from the fact that an abiding ovarian disturbance may induce trouble in the neighbouring organ or *vice versâ*.

The last point in this connexion is one that I am sure will be at once agreed to by everybody in this room and it is this. If there is one solitary factor in the production of appendicitis which is overwhelming it is a loaded cæcum. I really think it is a little exaggeration, but not a gross one to say, that if loading or overloading of the cæcum could be avoided there would be exceedingly little appendicitis. That is so almost uniform a feature of this trouble that one need hardly go into the history of some of the cases. You know what these histories are—a child with teeth overlapping, a man with no masticating teeth to eat meat, the commercial traveller who has his meals all over the country and eats and drinks and smokes too much, and a man who habitually bolts his food. Nothing plays, I think, so important a part in the prophylactic treatment of appendicitis as the recognition of the fact that if the cæcum can be kept free from indigestible food and undigested food the risk of attack is very much minimised.

With regard to clinical matters it would be a gross waste of time of this society if I were to deal in any way with the clinical phenomena of this common trouble. But in this connexion I want to deal with one solitary point—with the so called McBurney's point. Tenderness at this magic spot has become a sort of talisman; it is an inspired sign, it is a sort of religious stigma, it is the touchstone of the disease. The hand of the experienced man is put on the spot and there is tenderness and the patient has got appendicitis. I need not remind you where this spot is, but let me say what is said of it. It is said to be always present in every case of appendicitis, it is said to be not present in other troubles met with in the abdomen. It is said to indicate the seat of the disease, it is said by some to indicate the position of the diseased appendix. It is said by others who are more cautious—by McBurney to wit—that it actually indicates the precise space of the appendix. Well, now, that is the most modest account that could be given of the possibilities of McBurney's point. Beyond that there is a great deal more, but that is keeping soberly within the limit of fact. The construction that I would venture to put upon it is this. There is a certain tenderness in the right iliac fossa in appendicitis and McBurney's spot corresponds roughly to the centre of the right iliac fossa and therefore it is reasonably the place where tenderness is exhibited. Next it is a symptom quite common in other maladies, most notably in colitis. In the next place I should say that it is a feature exceedingly common in perfectly healthy individuals in a quite normal state. Last of all, it does not indicate the situation of the disease a[illegible] does not indicate, which McBurney insists that it does, [illegible]tuation of the base of the appendix. Any man ope[illegible] and cutting through the situation at this point will know [illegible]ctly well that there may be tenderness there and the base o[illegible]he appendix does not correspond to that spot. Feeling that it was a matter that needed investigation I asked Dr. A. Keith if he would carry on investigations on certain lines that I indicated and I am deeply indebted to him for the admirable manner in which these investigations were carried out. What struck me was this. So many persons are tender at certain points in the right iliac fossa and very often acutely tender. But there is no such point on the left side and there must be something, therefore, anatomically different there What is it? The ureter or what? This is how the facts come out. Sections were made along the spino-umbilical line; that line measures in the normal male adult six inches and it crosses the rectus muscle at the anatomical point known as Munro's point and it roughly corresponds there to McBurney's point. Well, now, the ureter has nothing to do with Munro's point because it does not cross the line there. Exactly the same condition exists on the left side, so that nothing is to be learnt from that. The next thing is this. The structure that exactly comes beneath that point is the ileo-cæcal valve. The tender thing that can be discovered in the body of a healthy person at that exact spot is the ileo-cæcal valve. As you know, all orifices are peculiarly well supplied with nerve fibres and are peculiarly sensitive, such as the sphincter of the anus, the orifice of the pylorus, and other sphincter-like openings. That that is the cause of the tenderness in that particular spot admits of no dispute. The base of the appendix, you will be surprised to hear, is one inch below McBurney's point, as discovered in 50 bodies prepared by formalin. Dr. Keith was good enough to examine the bodies of 27 living medical students with this result:—in 11 the point of tenderness was exactly on the point; in nine it was a little above the point; and in four it was a little below the point. Those data pretty nearly correspond *pro rata* with the condition found in 50 hardened bodies by formalin. Moreover, in only three out of 27 students was there any particularly tender spot in the right iliac fossa; in none was there any tenderness discovered on the left side of the body. That, I think, should render definite the circumstances about McBurney's point and the part it plays in this trouble. Any medical man present who has examined in detail cases of colitis will well know the extraordinary tenderness there is often discovered and maintained at McBurney's point.

I want at this stage to say one word about phantom appendix—an appendix described as vertical, of the size of your little finger, and sometimes lying obliquely. That appendix is a phantom and it is a curious phantom. The vertical appendix is due to constriction of the uppermost fibres of the rectus muscle that can be often excited by stimulating the nerve as it enters the muscle. I need not remind you that the appendix, the cæcum, the peritoneum surrounding them, and the muscles of the abdomen which cover them and the skin which covers these muscles are all supplied by one nerve, in the main the eleventh dorsal. Even when the patient is under anæsthesia a little hard pressure in that spot where the nerve enters the rectus muscle will bring out this vertical appendix.

In order not to take up too much of your time I think I might finish what I have to say by dealing with what, after all, is the most interesting part of my subject—the operative treatment of this trouble. It is most remarkable that this subject, which one would think is simple enough, is perfectly bewildering by divergent opinions coming from men whose authority one cannot repudiate and must recognise, and added to this is the difficulty that we are still entirely lacking in reliable statistics. What is the general death-rate from appendicitis? Of course, hospital cases are cases of certain gravity and in those cases the death-rate is estimated at something like 15 per cent. But take 10 medical men who have practised in a large town for, say, 20 years and therefore must have had to deal with a great many cases of appendicitis. What number have they lost in that period? They would be shocked at the suggestion that they had lost 15 per cent. It is impossible, therefore, to get quite at the figure. But records have been obtained casually from practitioners and also from the German army in time of peace. It is curious that in both these instances the figure comes out at 5 per cent. I know that this figure is open to dispute, but still I do not think that out of 100 cases of appendicitis I have lost more than five in the course of my private practice. I think, therefore, that 5 per cent. may be accepted as the general rate of mortality in appendicitis. When one goes further into the question of operative treatment of appendicitis the whole crux is, What is to be done during an acute attack? There are certain men whose opinions must be listened to who assert that you must operate in every case of appendicitis as soon as the diagnosis is made. I know that that is not perhaps quite the common position taken up by surgeons in this country, but, as you know, it is almost universal—at least, in America. An operation, they say, should be carried out as soon as the diagnosis is made—not on the second, third, fourth, or fifth day. There are others who operate only on compulsion; they say, "No, the majority of the patients get well," and they only operate in exceedingly acute cases in which pus is evident or in cases that are really spun out and going to such a length that they feel there must be some condition within the iliac fossa which can only be reached by operation Those are the two sides of it.

Speaking from no other than the very uncertain basis of one's own experience I would take the opportunity of submitting these isolated points to your consideration, believing that they form the basis upon which something like a sound opinion can be arrived at. First of all there are advocates of what may be called indiscriminate operation. They use terms of this sort—"You must operate; the appendix is ruptured, there is perforation, there is acute peritonitis, there is gangrene." And mark—and this is the point that I want to draw attention to—these expressions are used exactly in the same sense as you use such expressions as "There is perforation of the bowel, there is a perforating ulcer in the stomach, there is gangrene or hernia of the intestine." And so they say an operation must be carried out even before a reasonable diagnosis has been made, as soon as an attack is suspected. What I very seriously object to is this that the two things are put in the same category It is an absolutely false analogy and distinctly misleading Is it for one moment reasonable to put perforation of the appendix in the same category with perforation of the stomach? It is monstrous. Not only can a perforation of a fair size occur in the appendix but a fair degree of gangrene may be met with without causing serious symptoms. I have found a concretion lying outside the appendix one month after an attack, when all the symptoms have subsided and without a single drop of pus. That must have been due to rupture of the appendix or perforation of the appendix or, if you like, gangrene of the appendix. Is it very reasonable, therefore, to use those terms in the same sense as you use the term rupture of the bowel, gangrene of the ileum, or perforation of the stomach? The analogy is absolutely unjustifiable. The second fact that I do not think can be pressed too strongly is this. The very great majority of all cases of appendicitis get well spontaneously I am speaking of a whole series of cases which come under the care of a medical man in general practice, and I think that it may be said that we are not very far from the truth when we say that the death-rate from appendicitis is 5 per cent. The third fact, which I think should be emphasised as strongly as the last one, is this. operation during an acute attack of appendicitis is attended with great risk to life. What that risk is we again have great difficulty in expressing in figures because they are not easy to get hold of. But we must take things as they are, and I have been at infinite pains to go through records by hundreds and the death rate in cases of operation—I do not say what operation—during an acute attack comes out at about 20 per cent. Some of the hospital records come out higher than that. The fourth point is a little by the way Relapses may occur after an operation carried out during an acute attack and that is a thing which must not be quite pooh poohed The last thing which I should like to impress upon your memories in very large letters, so to speak, is that the removal of the appendix during the quiescent period is attended with infinitely small risk.

If these facts are admitted—perhaps you may say they are not accurate or they are distorted, but I do not think they can be very much out of what is actually the fact,—if these facts are accepted, then I think the line of treatment is not difficult to establish and may be pretty clearly defined Acting upon what one believes to be the best information that the records at present provide in the various directions that I have indicated I think one comes to some such conclusion as this. all that we know of the pathology of inflammation of the appendix is positively opposite to the teaching that operation should be carried out the moment the diagnosis is made. I think that that cannot be put too strongly We know a good deal about the pathology of this trouble and I think that what we do know will not support the dictum that as soon as the diagnosis is made operation should be carried out. The second point is this. An immediate operation should be carried out in all the ultra-acute cases. It is often said that you cannot diagnose them. I would venture to controvert that statement. I believe all these cases are easily recognised, although there are two perfectly distinct types of these ultra-acute cases. There are some in which the local manifestations are not very striking and where the overwhelming symptom is that the patient has introduced into his system a gigantic dose of poison, with a temperature of 104° or 105° F., with the pain not very striking. Those are cases of septicæmia of the most intense character and the patient dies, perhaps, within 36 or 48 hours. In such cases the operation will probably do no good, but it can do no possible harm and it should be as a matter of positive routine carried out. The second class of acute cases also cannot be mistaken. It is exactly parallel to perforation of the stomach and I do not think anyone can have any difficulty in recognising the acute peritonism. The ultra-acute cases cannot be operated upon too soon. The third proposition, which I hope also will meet with your approval, is this an immediate operation should be carried out as soon as there is any suspicion of pus. I suppose that will be universally accepted. I do not want a demonstration of pus but a reasonable suspicion of it.

If those three propositions are accepted that takes us a long way What, then, with regard to the residue of these cases which represents the great mass of cases of appendicitis? I have excluded all the ultra acute cases and I have excluded those cases in which there is pus, and I think that in the cases that remain it is seldom imperative that an operation should be discussed until about the fifth day I think that you will agree with me that in a case of appendicitis, if the temperature comes down and is getting towards normal about the fifth day your anxiety is becoming comparatively slight. And because the temperature keeps up after that day the case is not necessarily doomed, though very probably it will have to be dealt with. Having excluded the cases that I have mentioned I think that the phenomena associated with this malady will bear out that somewhat moderate suggestion in the matter of practice that the surgeon should hold his hand until some such time as the fifth day has been reached when the requirements of the case will have been made quite manifest. Another matter that I will trouble you with is with regard to operative treatment carried out during the quiescent period. It so happened that in a paper which I read before the Royal Medical and Chirurgical Society in 1887 I ventured to suggest that appendicitis when relapsing should be treated by removal of the appendix during the quiescent period. Looking back on the discussion which followed that paper it is curious to note how very feebly it was received and how the method advocated therein was scarcely accepted at all as a reasonable method of treatment. In that particular discussion one physician of considerable experience said that in the whole of his life he had never seen a case of typhlitis that could possibly have called for surgical interference of any sort. So that the reception of that paper was one which, I must confess, condemned me very much. Still, I do not think one has any reason to complain of the infrequency with which the operation is carried out at the present day I have since that particular date removed the appendix during the quiescent period over 1000 times and out of that number I have lost two patients. I could without being very Jesuitical exclude one of those cases because it was not primarily a case of appendicitis but where there was a mass in the right iliac fossa and where as a result the appendix was concerned. But I will acknowledge the two deaths.

The next point that I want to ask you to consider is this, and it is a difficult matter in practice When should this operation be carried out? A patient comes to you and says, "I have had one attack," and you might almost tell him that the operation is so trifling that he should have the suspected organ removed. But the whole question is summed up in this What is the probability of relapse? It is a curious thing that the percentage of relapses has greatly gone up. At one time there were said to be very few relapses—from 20 to 30 per cent. I am quite certain that it is safe to say nowadays that the great majority will relapse. Therefore I think it could be put down, as a line to guide one in directing this matter, that it is desirable to remove the appendix after the first definite attack. The line of argument is this. In the majority of cases there will be a relapse and the patient must feel that the weight of figures is against him. Secondly, the risk of the operation is really almost infinitesimal and will in time become quite trivial. There is just this little sort of comment to be made on a bold assertion of that kind. If there has been an abscess in the first attack then I think an operation may be put out of court altogether because that abscess will in certainly 95 per cent. of the cases obliterate the organ and render it harmless.

Well, then, I have been frequently asked this question: What has been your experience of cases that do not relapse? Going back as I can now over some years, and having seen some thousands of cases of appendicitis, I have seen a great many patients who have had only one attack and having known their career for a number of years—I do not want to quote them as exceptions to any rule but to put them forth as cases in which perhaps that rule may be subjected to consideration and perhaps relaxed—my experience has been this. I have seen children in whom an attack of appendicitis has distinctly followed the lodgment of some mass in the cæcum. In one such case the child ate a lot of nuts and had appendicitis with cramp and hardness over the organ. In that case where there has been only one solitary attack following the lodgment of some mass in the cæcum the child may never have another attack unless it repeats the same alimentary performance. The other class of case is this: the adult who has a great many errors in the matter of feeding to correct. For instance, the commercial traveller who perhaps has no masticating teeth eats anything he comes across at all times of the day: lunches at one, two, or three o'clock, rushes into the bar with his hat on the back of his head, eats anything that happens to present itself, bolts it, and goes about his business in an atmosphere of tobacco and alcohol. That man has gross dietary errors to correct and if they be corrected that man may never have another attack. I think that in the consideration of cases of appendicitis the circumstances in those two classes of the disease that I have mentioned must be taken into account. I might, perhaps, just quote one such case. A medical man was working in a colliery district under the very worst possible conditions. The man was up day and night and got his meals anyhow, and he practically had no masticating teeth. He was a man temperate in every respect. Eventually he inherited a fortune, a very large sum of money, and of course the very first thing he did was what any of us would have done—he abandoned the profession and sought opportunity for rest. Previously he had had one attack of appendicitis and he now came to me saying that he wanted to have some enjoyment out of life and he thought that the first element of success in that direction was to have his appendix removed. I thought that perhaps he might make a little cult of his appendix, so it was agreed that it should not be removed. That man observed the general rules of health and I see him occasionally and he has never had a single attack since. With regard to chronic appendicitis I think that in every such case the appendix should be removed when there is no other treatment for it.

Last of all I must say this: the removal of the appendix is not a panacea for every ill in the lower part of the abdomen, because there is apparently an impression abroad in the present day that any kind of disturbance below the umbilicus must of necessity involve the removal of this very much discussed organ.

The Hunterian Lecture

ON

SOME POINTS IN PRACTICAL SURGERY SUGGESTED BY THE STUDY OF THE LIFE AND WORK OF JOHN HUNTER.

Delivered before the Hunterian Society of London on Feb. 26th, 1902,

BY REGINALD HARRISON, F.R.C.S. ENG.,
SURGEON TO ST. PETER'S HOSPITAL, LONDON; CONSULTING SURGEON TO KINGSTON DISPENSARY AND BRAINTREE COTTAGE HOSPITAL.

MR. PRESIDENT,—When your predecessor asked me to deliver the Hunterian Lecture this year I felt less diffidence in accepting the honour than I should otherwise have done because I knew that your society had never ceased to show its reverence for the illustrious man whose name it bears in the most practical and useful forms.

I am taking for my subject some points in practical surgery suggested by a study of the life and work of John Hunter. It would be difficult to find a more agreeable or improving occupation than that of recognising and tracing how much we are indebted to him for the rapid strides our art has made in almost every direction. Though Hunter did not give us anæsthetics or antiseptics, he prepared surgery, by placing it on a scientific basis, for the reception of these two grand discoveries of this age.

[Mr. Harrison proceeded to show that Hunter's teaching as to the cure of hydrocele was true even of the present day. He proceeded:]

Hunter's observations on perineal urinary fistula are interesting. He says: "In whatever part of the urethra the disease is the external opening seldom heals as long as the seat of the disease has no disposition to heal. Let us compare this disease (urinary fistula) with the state of parts after lithotomy. If the incision is made in sound parts, and the whole injury be a stone which is extracted, the parts readily heal in spite of the urine passing through that channel. This, then, shows that there is another cause of their not healing." Further he states: "To cure this disease it is necessary first to make the natural passages as free as possible, that no obstruction may arise from that quarter—and sometimes this alone is sufficient—for the urine finding a free passage forwards is not forced into the orifice and the fistula heals up. But the dilatation of the stricture is not always sufficient; it is often necessary to perform an operation on the fistulæ when they alone become the obstacle to the cure." Here we have in a few lines the pathology and treatment of urinary fistula with a reservation for exceptional or complicated cases. There can be no doubt that in the larger proportion of cases where a stricture of the urethra co-exists with a urinary fistula, or is the cause of it, the removal of the stricture by some form of dilatation, with or without the retention of a catheter, as Hunter suggests, is sufficient in itself to effect a cure of the fistula, and so long as the patient is careful in keeping the stricture dilated such a consequence is not likely to recur. But this consideration by no means covers the whole ground. Water or urine will invariably escape through the easiest channel. Cases are frequently met with where it has thus been found impossible to heal up these sinuses even though the stricture has been fully dilated. This would seem to imply that either owing to a state of urethral spasm to which persons are more liable who have had obstructions of this kind, or, as Hunter suggests, to the precise manner in which the false routes communicate with the urethra, it is impossible to prevent some urine from entering them during the voluntary act of micturition. Either of these reasons is sufficient to explain this difficulty in closing a fistula.

Then arises the question, What more can be done to bring about a closure of these fistulæ? for nothing can be more intolerable to a patient than having to go about with a leaking and discharging sinus that fails to heal. Hunter's reference to the making of wounds which "readily heal in spite of urine passing through them," to use his own words, has an important bearing upon this point, for it will be recognised that their substitution for those which show no tendency to repair, but, on the contrary, to remain patent as suppurating and offensive sores, may often be advantageously utilised. This point has frequently been demonstrated in practice, and proved the quickest and safest way of dealing with certain forms of urethral stricture complicated with one or more urinary fistulæ. Thus the secondary proceedings to which Hunter refers—namely, operations on the fistulæ themselves—may be obviated as unnecessary when the stricture is entirely freed and the urine so efficiently drained as to be prevented from entering unnatural channels. And it is upon the two governing principles as laid down by Hunter in the passage quoted as being generally applicable to this class of cases that I would desire to lay stress. These are (1) the necessity of securing a free outlet forwards for the urine, and (2) the provision of a wound when required for this purpose which will, as Hunter states, "readily heal in spite of urine passing through it."

I have already observed that in dealing with the expulsion of urine from the bladder it must be remembered that its course is entirely determined by the degree of resistance that is opposed to it. If this is less in the case of a false or an unnatural route it is certain to select this in preference to the natural channel, whatever may be the condition of the latter. Hence to divert the urine from these fistulous openings and cause them to dry up and heal from want of use it is a first principle to secure its escape by the natural channel, or, if the latter is permanently damaged, by a substitute. In the matter of urine drainage much depends on the nature and position of the wound that is made for this purpose. We see this, for instance, in the case of wounds made for median lithotomy as compared with those made for lateral lithotomy. The former will not drain thoroughly and incontinently without a suitable drain-pipe or other apparatus. The latter is entirely independent of all kinds of apparatus and the drainage will be free and incontinent until repair has made considerable progress. I do not think sufficient has been made of this distinction.

Hunter says, when speaking of the effects of enlargement of the lateral lobes of the prostate: "A small portion of it which lies behind the very beginning of the urethra swells forward like a point, as it were, into the bladder, acting like a valve to the mouth of the urethra. It sometimes increases so much as to form a tumour, projecting into the bladder some inches. This projection turns or bends the urethra forwards, becoming an obstruction to the passage of a catheter, bougie, or any such instrument, and it often raises the sound over a small stone in the bladder so as to prevent its being felt." In such cases, he remarks, "I have frequently passed first a hollow elastic catheter till it has reached this point, and afterwards a stylet or brass wire properly curved so as to go over the prostate gland."

Hunter gives a very sound piece of advice in reference to the importance of surgeons instructing patients who are liable to urethral obstructions or to enforced retention of urine in the art of passing a catheter for themselves. He observes: "This practice of the patient under a surgeon's eye, by which he is taught how to pass them, becomes more necessary as strictures are diseases that commonly recur; and therefore no man who has ever had a stricture and is cured of it should rely on the cure as lasting, but should be always prepared for a return, and should always have some catheters with him. He should not go a journey, even of a week, without them, and the number should be according to the time he is to be absent, or to the place whither he is going, for in many parts of the world he cannot be supplied with them." No better counsel could be given than this. Now, however, it would not be regarded as complete without attaching instructions as to the necessity for employing scrupulous care in cleaning these instruments and rendering them innocuous, so far as this is possible, by the use of antiseptics.

In reference to the latter subject I cannot find that Hunter recognised as possessing any striking peculiarities what at the present day we are accustomed to speak of as urinary fever. It would be very interesting, Sir, if at your bidding we could hear from him his opinion as to its etiology. Which view would he take—the neurotic or the septic, or would he recognise both? It is a difficult question to determine and much variety of opinion in reference to it prevails. For my own part I cannot see how and where the nerve theory of causation comes in, though I fully recognise how largely the sexual apparatus is innervated and how sympathetic it is. I would ask what have been the results of the extension of the principles of antiseptics to the surgery of the urinary organs? What has followed the more stringent precautions that we as surgeons impose upon ourselves in all that applies to the use of instruments to these parts? and what happens commonly when we or our patients fail in giving the fullest effects to these antiseptic provisions? Have we thereby lessened or increased the number of cases which would come under the designation of urinary fever? Again, how does it happen that the most frequent and fatal forms of urinary fever are associated with the smaller lesions and not with the larger? How insignificant must be the nerve damage which is occasioned by an internal urethrotomy or the passing of a sound or catheter as compared with that of a lateral lithotomy for the removal of a large calculus, as used to be practised. And yet after the latter we seldom, if ever, saw anything more than the febrile excitement which is usually associated with all wounds which are not protected by antiseptics. Again, an unprotected internal urethrotomy wound is almost invariably followed by a rigor and some degree of urinary fever. Whereas if we considerably add to that lesion by a perineal section for the insertion of a drainage-tube into the bladder, no urinary fever follows if the latter acts perfectly. Lastly, what has sterilisation of the urine done in reference to the liability to urinary fever? The late Dr. Palmer of Louisville, whom I knew well, showed how by sterilisation of the urine by administering boric acid beforehand, the liability to this fever was almost reduced to *nil* in the case of such operations as internal urethrotomy. By evidence of this kind the septic origin of urinary fever is, I believe, substantiated as against the nerve theory.

The question which I have thus raised as to the etiology of so-called urinary fever is one of much importance, for if it is septic, as I believe it is, it should be amenable to precautionary antiseptics. For some time I have been acting on this principle. If I ever cause, either accidentally or designedly, a lesion of the male urethra, as by passing a sound or a catheter or in performing an internal urethrotomy, I am in the habit of putting some antiseptic into the bladder immediately after, which would seem to have the power of temporarily sterilising the urine and rendering it less likely to infect the individual through any small lesion that may have been caused. For instance, after an internal urethrotomy on completing the operation I put into the empty bladder some ounces of boric lotion or of a solution of corrosive sublimate, the latter in the proportion of 1 in 6000, and leave it there. In this way I believe that I have succeeded in averting the absorption by the wound of intensely poisonous compounds derived from the urine, probably of the nature of ptomaines, which indicate their presence in the system by the characteristic rigors and elevation of temperature with which, unfortunately, we are so familiar. By following this local treatment up by the internal administration of certain drugs which more or less sterilise the urine, as in Dr. Palmer's experiments with boric acid, the development of urinary fever in this class of operation may often be prevented. The best sterilisers for this purpose are urotropine, benzoate and salicylate of soda and borocitrate of magnesia. The last-mentioned is the only digestible preparation of boric acid I know of which can be given in sufficiently large doses to effect this purpose. Quinine and salol have a similar action, but they are not so well adapted as those mentioned.

We would do well if we paid more attention to the subject of urine sterilisation in its relation to the prevention and treatment of urinary fever, in connexion more particularly with some of the minor operations on these parts. In some surgical works hardly any reference is made to this as a necessary part of the preparatory treatment of persons about to undergo operations involving these organs. Hence urinary fever and the complications arising out of it, such as suppression of urine, are far commoner than they should be.

Hunter, when evidently speaking of the treatment of residual and retained urine in cases of enlarged prostate, makes a very pertinent observation. Referring as to how the urine may be evacuated in these circumstances he says: "There are three ways in which it can be done, one by allowing the parts to do their own business as much as they can, and this at first sight might be supposed to be the very best, but it is in some cases the very worst." He gives prominence to the view, now as then entertained, that there is some degree of positive risk connected with non-interference in cases of this kind which may arise from persons carrying about with them constantly that which ought to be spontaneously evacuated. Where this can be done with impunity and where it is attended with more or less risk is sometimes a fine point to decide, but it is one that should always have our careful consideration.

No one, I am sure, would wish to introduce a patient to what is called catheter life—for life it usually is—prematurely or without sufficient reason, but the necessity for the use of the catheter under certain conditions of bladder unrest and urinary change should not be overlooked or disregarded. States of exhaustion and sepsis may thus be imperceptibly impending. Because an elderly man carries about constantly with him two or three ounces of normal urine is not sufficient reason why he should use a catheter. On the other hand, an ounce or so of decomposing urine contained within the bladder in some depression or sac may readily prove a source of infection which should be removed and dealt with, for thus the whole amount of urine may be rendered offensive and poisonous.

Amongst the many subjects that Hunter occupied himself with were the periodical changes which took place in the sexual glands of birds and certain mammals. In some observations on the function of the prostate gland in man and the lower animals Mr. Joseph Griffiths of Cambridge quotes the following from Hunter's works: "The prostate and Cowper's glands and those of the urethra in the perfect male (bull) are soft and bulky. In the castrated animal (bullock) these are small, flabby, tough, and ligamentous, and have little secretion. Especially marked is the change when the animal is castrated when young."[1]

Passing from these observations, I will proceed to notice some points connected with the surgery of this part. I do not think there can be any doubt that there are various states of obstruction arising out of prostatic hypertrophy where it is impossible to give adequate relief to the patient by the use of the catheter, however skilfully it may be employed. Further, there are instances where persons, either from sentiment or more cogent reasons are willing to incur some degree of risk to their lives to escape the annoyance of catheter dependence. For many years it has been laid down as a guiding principle that persons so situated by reason of an obstructing prostate should be content with their lot so long as the process can be carried on with a reasonable amount of ease and satisfaction to themselves. This principle seems to have been arrived at on the following grounds: first, because catheter dependence is not inconsistent with the maintenance of good health and the attainment of an average existence or even a life considerably exceeding this limit; and secondly, because the removal of more or less of the prostate did not necessarily mean that normal micturition would in all cases be permanently restored.

---

[1] Journal of Anatomy and Physiology, vol. xxiv.

Evidence seems to be accumulating to indicate that prostatectomy may be practised with greater safety and certainty than it was formerly. This is due, partly to improved methods of operating and partly to our recognising more fully the varieties of form and structure which the hypertrophied prostate presents. Our desire to discover some uniform method of treatment appeared to retard the surgery of this part, for I have little doubt that Dr. William White's important suggestions and practice relative to the induction artificially of shrinkage of the prostate tended in some measure to draw our attention from Mr. McGill's work long before we had acquainted ourselves with all its merits and were sufficiently informed as to its limitations.

It would be premature at present to draw conclusions from figures relative to the more recent developments of prostatectomy. Taking, however, cases where the enlargement is mainly due to what may be spoken of as enucleable adenomas[2] which by their early and somewhat rapid development appear to have squeezed out of existence, even to the limits of the fibrous capsule, the original prostatic tissue, the mortality is not large. Fuller[3] writes: "The mortality attached to prostatectomy is at the present time (1900) in the neighbourhood of 15 to 18 per cent. If one operated simply on selected cases it ought to be much less." My colleague Mr. P. J. Freyer[4] has recently published the results of eight cases with one death at the end of three weeks. These cases are of much interest and importance and have undoubtedly given a fresh impulse to enucleation in connexion with suprapubic prostatectomy. Mr. H. L. Barnard[5] has recorded two cases, both successful, whilst from my own practice during the past year I can mention five cases without a death, as yet unpublished, and in the practice of some of my colleagues five other cases, also unpublished, without mortality and with excellent results.[6] Within my own knowledge, therefore, I can bring forward a series of 21 cases in which this operation has been performed with only one fatality. It is hardly fair, perhaps, to take such a limited number of cases as the basis of a statistical statement, but it will be seen that far from Fuller's mortality of 15 to 18 per cent. being reached, the mortality in this series only totals 5 per cent. Even the last figure is capable, I believe, of a further reduction by utilising the less formidable process of urethral prostatectomy as will first be illustrated, or by substituting perineal tubing with control drainage[7] in cases physically or otherwise unfitted for vesical prostatectomy. Nor should I omit to mention a paper published by Mr. Mayo Robson,[8] which included 12 cases of prostatectomy with one death. From a different standpoint Professor Albarran,[9] of Paris recently recorded 16 cases of perineal prostatectomy which he had completed without a death. The operative prospect from all sides may therefore be regarded as favourable. Viewing these figures as a basis representing the results of prostatectomy and comparing them with what happens to persons leading a catheter life, I am inclined to think that they favour the former rather than the latter. Take, for instance, the man who has to catheterise himself 1000 times or more in the year. What is his expectation of life as compared with the individual who incurs the risk of a prostatectomy and has, after a successful operation, no further need for this instrument? I am disposed to think, from long observation and knowledge of persons habitually using and dependent upon catheters, that they eventually succumb to one or other of the casualties incidental to this form of instrumentation.

Then, again, our views relative to the paralysed atonic bladder associated with the hypertrophied prostate certainly require remodelling under the light that prostatectomy has thrown. There can be no doubt that after this operation persons have completely recovered natural bladder power after its suspension for from one to seven years. The possibility of this has been doubted and more than once publicly challenged. A reference to such records as I have mentioned is sufficient, however, to support this statement.

Time will not permit me to speak of the relationship, which Hunter was the first to point out, that existed between the testes and the prostate and to offer some remarks on the employment of vasectomy in connexion with some forms of urinary disorder. I refer more particularly to the influence which this operation may exercise in preventing and arresting prostatic enlargement in a very simple manner, and further, in interrupting the extension of inflammations and other microbic conditions from above downwards and *vice versâ*. These observations have already been placed before the profession and are utilised in practice. I will therefore pass on to notice the application of prostatectomy to some cases of enlarged prostate complicated with vesical stone.

As matters at present stand there can be no question that in the case of stone in the bladder happening in young children and adults before the prostatic age is reached its removal should be effected by crushing, save under exceptional circumstances. When, however, the period is reached when prostatic hypertrophy may be the cause or the complication of a bladder stone the liability to recurrence after removal by crushing becomes exceedingly frequent and has to be taken into consideration.

In early days my practice, so far as the operative treatment of stone was concerned, included a considerable number of young male children, and I remember tabulating a large number of lateral lithotomy cases in these subjects, with a record of "no deaths and no recurrences." More recently I published a paper[10] which included an analysis of 110 persons upon whom I operated for stone in the bladder during the years 1890–97. This comprised 101 litholapaxies, three perineal lithotrities, two suprapubic lithotomies, and four median lithotomies. Of the 101 litholapaxies or crushing operations, though the mortality was only a fraction over 5 per cent., 23 of the patients were known to have one or more recurrences for which I treated them on subsequent occasions. These occurred for the most part in persons of an advanced age with enlarged prostates who were more or less dependent on their catheters and possessed but little power of voluntary expulsion. Thus by trapping gravel and concealing fragments of grit, prostatic hypertrophy considerably adds to the liability to vesical stone and its recurrence in the later portion of male life. For reasons of this kind many surgeons have considerably restricted the use of litholapaxy, and have substituted for it suprapubic cystotomy. Writing to me recently on this subject and in view of a reduced mortality after the latter operation, Mr. W. Cadge states: "I should, were I still in active practice, do abdominal cystotomy, not only for large stones, but for cases in which the stone is of moderate or small size, the patient depending wholly on the catheter, the prostate large, and the bladder misshapen or pouched; for cases, in short, which constitute the large proportion of recurrences." The more recent developments in prostatectomy will, I think, add considerably to the force of Mr. Cadge's remarks.

In persons suffering from much enlargement of the prostate and catheter dependence, complicated with stone in the bladder, after litholapaxy has failed once, or perhaps twice, to prevent recurrence of the latter suprapubic cystotomy will have still further claims for consideration, not only because it permits of the removal at one operation of the stone, but a contributing cause of it, as well as the catheter dependence, which so frequently coexists or arises under these circumstances, I will proceed to illustrate the employment of prostatectomy by the narration of a few cases and to show what was thus removed.

[10] "A Further Contribution to the Surgery of Stone in the Bladder," op. cit.

CASE 1.—The following case may be taken as illustrating, not any difficulty connected with the removal of stone from the bladder by crushing or litholapaxy, but two conditions favourable to the formation and recurrence from time to time of phosphatic stone when an enlargement of the prostate is present. These were (1) the necessity existing for the permanent use of the catheter which implied the suspension of the voluntary power of urine-expulsion and whatever else the bladder contained, and (2) a specially foul state of the residual urine which co-existed and supplied a material for stone formation. The case further illustrates how the removal of the obstruction thus caused by the prostate ended these two conditions. The patient, aged 55 years, was seen with Sir R. Douglas Powell in April, 1899, with symptoms of stone in the bladder for which he was sounded A stone was felt lying behind a prominent prostate. I removed the former by litholapaxy, the fragments weighing 296 grains of oxalate and phosphatic stone. The patient previously to the operation had been largely dependent on his catheter for a year and it was hoped that the removal of the calculus would be followed by a return of natural power This, however, was not the case, though in other respects he made a rapid recovery after the operation. A recurrence in the form of a phosphatic stone took place and he was again operated upon in August of the same year by litholapaxy A second recurrence occurred later and a stone was removed in a similar manner in September, 1900 Early in 1901 he had further symptoms of stone and it appeared clear that the only way of preventing these recurrences and restoring the natural function of micturition was to remove the obstructing portion of prostate. A careful examination was made by the cystoscope and I recognised the conditions outlined in the illustration (Fig 1). It will be seen that two stones were covered by an *overhanging middle lobe, with a narrow or* stalk like pedicle Thus both gravel and urine were trapped. Guided by some previous experience of a similar kind I recognised that this form of prostatic obstruction could be completely removed without opening the bladder, an important point. I therefore punctured the deep urethra on a grooved staff as for a median lithotomy and introduced my finger into the bladder. Having thus made my way I substituted a pair of polypus forceps, and seizing the neck of the growth twisted off the excrescence as figured and afterwards withdrew the two stones which are delineated beneath it (Fig 2). A drainage-tube was introduced into the bladder and retained for a few days, on the withdrawal of which the small wound speedily healed. He left the surgical home on the fourteenth day. He has never used a catheter since nor has he had any further recurrence of stone. He had been dependent on his catheter for over three years and never hoped after what he had been told to dispense with it. How far this form of prostatectomy succeeded may be gathered from my examination of his *bladder a year after* this operation. His urine was perfectly normal and he had no residual.

FIG 1

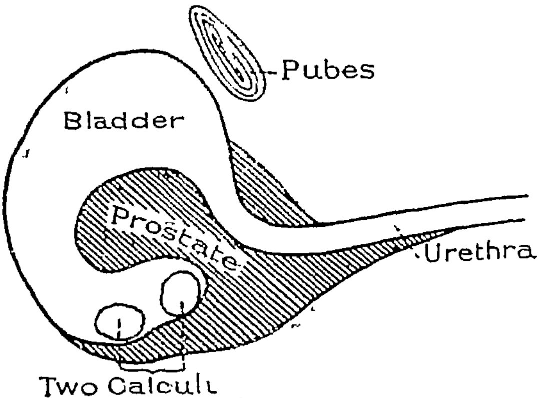

FIG 2.

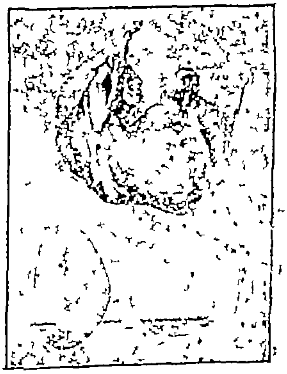


The growth proved to be a pendulous adenoma and no further enlargement is likely to take place. The case shows the importance of recognising those prostatic enlargements which can be dealt with without submitting the patient to a more extended operation. Dr J G Pardoe assisted me and Mr C Carter Braine gave the anæsthetic on these occasions.

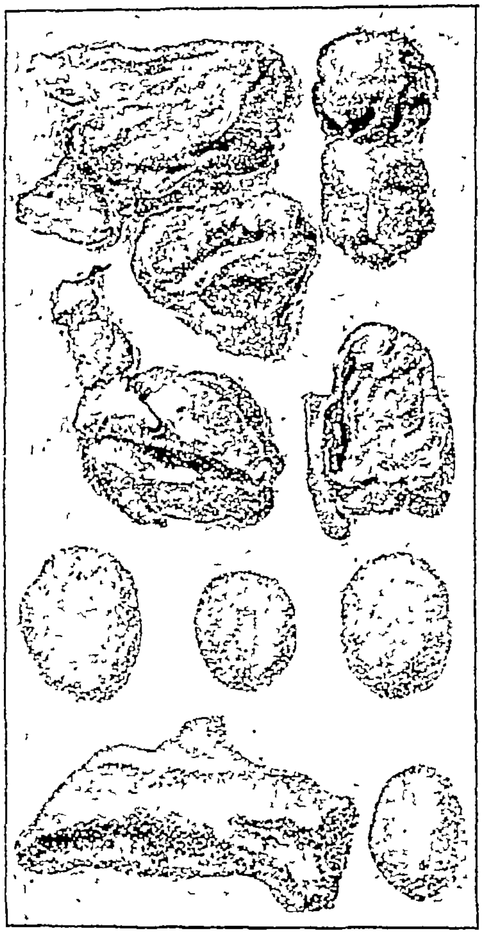
CASE 2.—The patient, a male, aged 79 years, was seen by me in consultation with Dr J G Glover. In 1897 I had removed a small stone from his bladder by litholapaxy His prostate was then considerably enlarged, and he was entirely dependent upon his catheter Attacks *of cystitis were frequent, and the difficulty connected* with the use of his instrument was constantly increasing When I saw him again in consultation in 1901 his condition was about as bad as could be imagined and his life most miserable. I advised suprapubic prostatectomy, which was done at once Dr Pardoe assisted me and Mr F W Braine administered the anæsthetic. The operation was a difficult one as the enlargement consisted of a prostate far advanced in fibrous degeneration and but little of it was enucleable by the finger However, a considerable mass was removed, partly by finger and forceps, and in addition the five stones, also figured below, weighing three drachms, which were completely concealed by overhanging growths (Fig 3). The patient *did remarkably* well and 21 days after the operation passed 40 ounces of urine naturally in 24 hours. He left the home at the end of four weeks and shortly after went to Bournemouth. His health is completely restored and he is again leading an active life. The case is a remarkable instance of how completely a person, even at this advanced age, can recover the normal power and function of the bladder After *seven years'* catheter dependence he has, been able to dispense entirely with this instrument and to exercise full control over urination.

[*Mr Harrison* gave particulars of three other cases of prostatectomy Concluding, *he said*]

Though the results of prostatectomy as now being practised are very encouraging, it must be remembered that instances of carcinoma of the prostate are liable to be submitted to this process. The diagnosis between a hard fibrous prostate and a cancerous one belonging to the malignant type is not always easy to make during life. Nor, as a distinguished microscopist once said to me, can this point invariably be readily determined even after death, except from a clinical point of view Yet the supposed rarity of cancer in this part must not be relied upon too much. *I have* already met with one instance in my practice, not sufficiently advanced *for* publication, where a carcinoma has been removed in these circumstances So far the case has done well and relief has been given, but what about *the future?*

In these remarks which I must now bring to a close, I have endeavoured, though very imperfectly, to illustrate by a few examples the influence that one man, in the person of John Hunter (who has now been dead over a hundred years), exercised on the development and progress of practical surgery. At no period in the history of surgery has this influence been greater or more conspicuous than at present.

FIG. 3.



The public and the profession owe a deep debt of gratitude to a society like this which devotes so much attention and attaches so great importance to all that relates to the life and work of John Hunter.

A NOTE UPON AMPUTATION AT THE HIP-JOINT.

BY EDMUND OWEN, F.R.C.S. ENG.,
CONSULTING SURGEON TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, W.C.

IN proportion to the gross number of amputations disarticulation at the hip-joint is, I suppose, performed more often at a children's hospital than at a general hospital. There are several reasons why this should be so. In the first place, cases of advanced hip-joint disease, for which the operation is often most admirably suited, naturally drift towards a children's hospital and the little patients as a rule rapidly pick up as soon as the hopeless limb is removed. Then sarcoma of the periosteum of the femur, for which disarticulation at the hip offers the only prospect of recovery, is particularly a disease of early life. Septic osteo-myelitis, also, which is peculiarly a disease of children, may require the high amputation.

I have assisted at the operation of amputation at the hip-joint, and I have performed it, a good many times and in a good many ways. The fact of there being many schemes for performing the disarticulation may be taken as evidence that there has been in the past no general recognition of there being any one operation of surpassing merit. Compression of the abdominal aorta by fingers or tourniquet, of the common iliac artery by the rectal lever, of the external iliac or common femoral by the fingers, or by a rubber tube applied in one ingenious way or another, or securing the vessels in the flap—each method of dealing with the main vessels has shown some evidence of defect, or, at any rate, has left a good deal to be desired. Then as regards the division of the soft parts—the planning of the flaps—there was the dashing method (particularly associated in this country with Liston's name) which gave a long anterior flap by transfixion; there were the methods by lateral flaps, and there were various racquet-shaped incisions. In later years came Furneaux Jordan's method of enucleating the femur through a long external incision and cutting through the soft parts in the middle of the thigh, or lower, the vessels having been controlled by the rubber band encircling the pelvis. This operation has, or rather the modifications of it which have been adopted from time to time have, much simplified disarticulation at the hip. But there is a still simpler method of operating, and it is the object of this note briefly to describe it.

First, the crural sheath is opened through an incision running vertically down from Poupart's ligament and the common femoral vessels are secured in separate ligatures. This takes very little time—not nearly as long as is usually taken to secure the superficial and deep femoral vessels and their bleeding branches in the cut flaps of an ordinary amputation. Then a circular sweep is made round the thigh a little above the middle, straight on to the femur, the bone being sawn through at the same level. Thus the limb is cut off square. An incision is next made on to the femur from the top of the great trochanter downwards and the bone is enucleated, some small branches of the sciatic, gluteal, or circumflex iliac arteries possibly requiring attention. If the amputation is being done for tuberculous or septic inflammation the periosteal and muscular attachments to the femur are separated with the utmost ease by a blunt raspatory, but if for peripheral sarcoma the surgeon would have to use a knife and to keep it well away from the bone.

Briefly, I would state my proposition thus: Amputation at the hip-joint is most conveniently performed after a preliminary ligation of the common femoral vessels by cutting straight across the thigh a little above the middle, and by enucleating the remaining part of the femur through an incision running down on to the bone from the top of the great trochanter.

Great Cumberland-place, W.

THE FIXATION OF MOVEABLE KIDNEY BY MEANS OF STRONG CARBOLIC ACID; SIX CASES.

BY THOMAS CARWARDINE, M.S. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON, BRISTOL ROYAL INFIRMARY.

THE method which I have adopted for nephropexy in the cases here recorded is, I believe, an improvement on methods in which scarification or peeling of the renal capsule is employed in association with other measures. It is applicable to all the recognised forms of nephropexy and gives greater security to their results.

The plan consists in freely painting the whole surface of the kidney, except the hilum, with the strongest liquid carbolic acid, so that the surface becomes covered with granulation tissue within a few days. The painting is best done after the supporting sutures, &c., have been inserted, but before they are tied, by means of a swab containing the liquid not in excess. In four of the cases—those in which the kidneys were suspended by gauze slings and packing—I have been able to watch the surface of the kidney for from 10 days to three weeks afterwards and I have observed the granulations and lymph rapidly form, followed by intimate and firm incorporation of the kidney with the surrounding tissues. The kidney could then be seen to move with respiration in conjunction with the parts surrounding it, and on pressing upon the exposed renal surface it was found to be inseparably attached even in those cases in which no sutures were used. Moreover, in a case treated thus combined with gauze packing I was able to verify the results a year afterwards, for on cutting through the old scar for the relief of pain of the liver in bulk (if needful, first drawing the organ downwards from under cover of the ribs) the whole of the gall-bladder and the cystic and common ducts are brought quite close to the surface, and as the gall-bladder is usually strong enough to bear traction, the assistant can take hold of it by fingers or forceps and by gentle traction can keep the parts well exposed, at the same time that, by means of his left hand with a flat sponge under it, he retracts the left side of the wound and the viscera, which would otherwise fall over the common duct and impede the view. It will now be observed that instead of the gall-bladder and cystic duct making a considerable angle with the common duct an almost straight passage is found from the opening in the gall-bladder to the entrance of the bile-duct into the duodenum, and if adhesions have been thoroughly separated, as they should always be, the surgeon has immediately under his eye the whole length of the ducts with the head of the pancreas and the duodenum. So complete is the exposure that if needful the peritoneum can be incised and the common duct can be separated from the structures in the free border of the lesser omentum, but this is not necessary except where a growth has to be excised. The surgeon, whose hands are both free, can now with his left finger and thumb so manipulate the common duct as to render prominent any concretions, which can be cut down on directly, the edges of the opening in the duct being caught by pressure forceps. The assistant can now take hold of the forceps with his left hand, as that instrument with the sponge will form a sufficient retractor since the duct is so near the surface. When the duct is incised there is usually a free flow of bile which it must be remembered is probably infective, but a sponge in the kidney pouch and rapidly mopping up the bile as it flows by means of sterilised gauze pads avoid any soiling of the surrounding parts, and if thought necessary the bulk of the infected bile can be drawn off by the aspirator either from the gall-bladder or from the common duct above the obstruction before the incision into the duct is made. After removing all obvious concretions the fingers are passed behind the duodenum and along the course of the hepatic ducts to feel if other gall-stones are hidden there, and a gall-stone scoop, the only special instrument that I use, is passed quite up into the primary division of the hepatic duct in the liver and quite down to the duodenal orifice of the common bile-duct, and, if thought necessary to insure the opening into the duodenum being patent, a long probe is passed into the bowel. The incision into the bile-duct is now closed by an ordinary curved round needle held in the fingers without any needle-holder, a continuous catgut suture being used for the margins of the duct proper and a continuous fine green catgut or spun celluloid thread being employed to close the peritoneal edges of the gut. In such cases, where the pancreas is indurated and swollen from chronic pancreatitis and is likely to exert pressure on the common duct for a time, I insert a drainage-tube directly into the duct and close the opening around it by a purse-string suture, the tube being fixed into the opening by a catgut stitch which will hold for about a week, but where this is not done I usually fix a drainage-tube into the fundus of the gall-bladder in the same way, as this drains away all infected bile and avoids pressure on the newly-sutured opening in the duct.

So easy is it to remove impacted stones after this method of exposure that I now never spend a long time in manipulating stones impacted deeply in the cystic duct, but at once incise the duct, remove the concretions, and close the opening without damaging the duct by much pressure and prolonged manipulation. Although there is seldom any fear of leakage or of infection, yet, owing to the separation of extensive adhesions, there is usually some tendency to pouring out of fluid in the first 24 hours. I therefore generally insert a gauze drain through a split drainage-tube, bringing it out either through a stab wound in the loin or forwards by the side of the gall-bladder drain The wound is closed in the usual way by continuous catgut sutures, first to the peritoneum and deep rectus sheath, next to the anterior rectus sheath, and, lastly, to the skin.

To those having little experience in this operation the modification which I have employed may seem trivial, but to those who have experienced the difficulties of the ordinary operation I feel sure that the method which I have described, which enables the whole of the bile passages to be dealt with as a straight tube close to the surface, will be sufficiently appreciated. But the technique of the operation is not the only important part of the treatment of these serious cases, which require thought and care not only before and at the time of, but subsequently to, operation.

A careful study of the causes of mortality in operations on the common duct shows that hæmorrhage, either immediate, consecutive, or secondary, cannot be ignored as a danger, and that shock apart from hæmorrhage has next to claim our attention. Sepsis is no longer the bugbear that it used to be, thanks to a rigid all-round asepsis, the employment of gauze drainage, and the careful avoidance of soiling the wound by infected bile. Although there is a greater tendency to bleeding in chronic jaundice from pancreatic disease than when jaundice is due to gall-stone obstruction I think there can be no doubt that in all cholæmic conditions the blood becomes so altered that the coagulability becomes seriously diminished and that these factors demand serious attention before any operation is undertaken in cases of common duct cholelithiasis. After reading Professor A. E. Wright's researches on the coagulability of the blood published in the *British Medical Journal* of Dec. 19th, 1891, my mind was prepared to grasp the possibility of turning the experience gained on dogs to practical uses in the human subject, as I had lost two jaundiced patients, one in 1888 and one in 1890, from persistent oozing of blood subsequently to operation. I therefore at once began to employ it in these cases and with benefit, but it has been only within the last two years, since using chloride of calcium in apparently heroic doses, that I have been able to get at the real value of the drug, which is the one I now always employ in the cases of jaundiced patients, both before operation in 30-grain doses by the mouth and afterwards in 60-grain doses by the rectum thrice daily for several days. The following case reported by Dr. W. Gough affords a good example of its utility.

A married woman, aged 38 years, was admitted to the Leeds General Infirmary on Jan. 23rd, 1901. She had had typhoid fever in September, 1899, and had never been quite well since. Shortly afterwards she began to suffer from biliary colic, though she had never been jaundiced till six months before admission, from which time jaundice had never left her. On Dec. 24th, 1900, she became much worse and had very severe paroxysmal pain, accompanied by shivering and profuse sweats. From that time she lost weight very rapidly and the jaundice deepened. On admission the liver could be felt below the ribs and there was a distinct fulness on deep palpation in the region of the pancreas. From Jan. 21st to the 31st she took calcium chloride in 20-grain doses thrice daily. Duodenocholedochotomy was performed on the 31st. There was very little bleeding. A stone nearly as large as a pigeon's egg was removed from the ampulla of Vater, which was laid open over a director introduced through the papilla at its opening into the duodenum. The head of the pancreas was felt to be much enlarged and hard. The incision into the ampulla was not sutured and through it the common bile-duct, very much dilated, was explored by the finger. The anterior wound in the duodenum was then sutured and the abdominal wound was closed. A drainage-tube was inserted through a stab wound in the right loin. The patient inadvertently did not have calcium chloride given in the nutrient enemata as is usual in these cases. She did well till the morning of Feb. 2nd, when the nurse noticed at 3 o'clock that the dressings were soaked with bright blood. The drainage-wound was exposed, but no hæmorrhage was occurring there. On examining the abdominal incision blood was seen to be slowly oozing from it and from the stitch punctures. One drachm of calcium chloride was administered at once by the mouth and three stitches were removed; the surface of the wound was then seen to be oozing all over. It was packed with gauze soaked in tincture of hamamelis and a firm dressing was applied. One drachm of calcium chloride was given again in two hours and afterwards it was repeated in 30-grain doses every two hours for six times, the drug being then given thrice daily. There was no recurrence of hæmorrhage and the patient made an uninterrupted recovery. The drainage-tube was removed on the 4th and she returned home within the month An examination of the blood showed a very marked diminution in the blood-plates.

I think that it is important to ligature all bleeding points and not to trust simply to forcipressure, and while in non-jaundiced patients adhesions may be simply separated, in these cases I prefer to divide adhesions between ligatures where practicable. Where there is persistent oozing of blood from innumerable points, a tampon of sterilised gauze forms

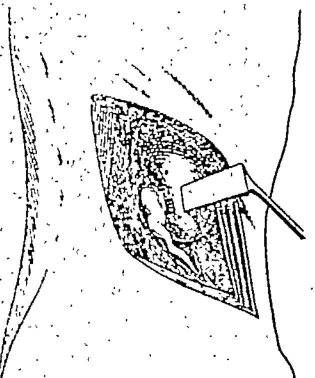
TABLE OF SIX CASES OF THE APPLICATION OF STRONG CARBOLIC ACID TO THE KIDNEY.

Case.	Date.	Age.	Cause.	History.	Method.	Remarks.	Result.
		Years					
1	Feb. 15th, 1898.	24	Congenital (?)	Paroxysmal pains as long as the patient could remember; nausea, vomiting, and dyspepsia two years.	Carbolisation; kangaroo - tendon sutures.	Several slight attacks of hæmaturia after getting up.	Reported as "quite well, no symptoms" 18 months afterwards.
2	August 9th, 1899.	18	—	Paroxysmal pains for two years, with nausea and constipation; frequent micturition.	Carbolisation; silk sutures.	Complete investing membranous capsule.	Gained much flesh and left the Infirmary free from pain. The patient has now been lost sight of.
3	Jan. 16th, 1900.	25	Lifting a wash-stand.	Pains increasing for six months "as if some-one gripped her loin;" vomiting.	Carbolisation; gauze slings above and below, gauze packing below.	Kidney bound to fatty capsule by strong adhesions.	Quite well for nine months, then the scar became tender and painful. The scar was incised 20 months afterwards and re-sutured in layers with complete relief. The kidney was then found to be inseparably fixed.
4	April 27th, 1900.	24	—	Pains in one loin. Tried a belt for 12 months. Unable to work.	Carbolisation; gauze.	Kidney small.	Now in service and "feels very much better than she had been for a very long time."
5	May 7th, 1901.	33	Lifting a heavy box seven years before.	Pains, tenderness, and a lump in the right side.	"	Kidney adherent to the fatty capsule and so moveable as to rotate with ease.	A year later reported "no pain in side or scar unless I overwork, then it passes off after rest."
6	Feb. 24th, 1902.	33	Lifting a bed a month ago.	Very severe pain since first acute attack in the right loin; intermittent tumour and polyuria.	Carbolisation; temporary suture of the kidney in horizontal axis; gauze packing below.	Upper ureter sinuously kinked and pressed upon by the lower end of the kidney.	Completely relieved from pain.

therein of six months' duration no differentiation of the scar tissue was visible until the cortex of the kidney was actually cut into, so intimate was the fixation. For these reasons I am very favourably impressed with the method of suspension with gauze (Senn) combined with cortical carbolisation which I have carried out in the six cases indicated below. There have been no disadvantages witnessed from the application of strong carbolic acid to the kidney and there has been a marked absence of post-operative pyrexia. One patient had temporary hæmaturia on leaving her bed, which I attributed solely to tight suturing. Hæmaturia is a recognised sequel to nephropexy.

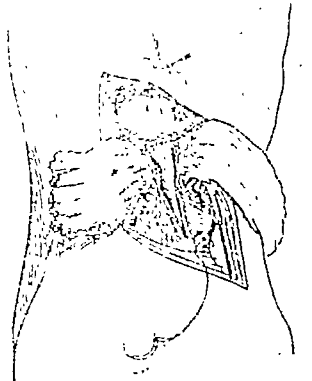
The last case was interesting from the demonstration it afforded of the mechanical conditions causing the hydronephrosis. When the kidney was freely exposed and lifted forwards (Fig. 1) the upper end of the ureter was found to be kinked and thrown into several folds and was also pressed upon by the lower end of the kidney in front of it. To correct these conditions it was found necessary first to place the kidney under the ribs and then to tilt it horizontally so that the lower end projected outwards to the wound (Fig. 2). Three temporary sutures, passing right through the parietes, were used to fix the lower end of the kidney in that position and then three pieces of gauze were lightly packed beneath the kidney, one anterior to the ureter, one behind it, and the third between them and reaching as far as the ureter. The sutures and gauze were finally removed at the end of three weeks.

FIG. 1.



Hydronephrosis: showing the kidney lifted forwards so as to reveal the contorted upper end of the ureter behind the lower end of the kidney.

FIG. 2.



The lower end of the tilted kidney suspended by temporary suture, thus straightening the ureter. Gauze is seen placed in front of and behind the ureter. A third piece was placed between the two prior to parietal suturing.

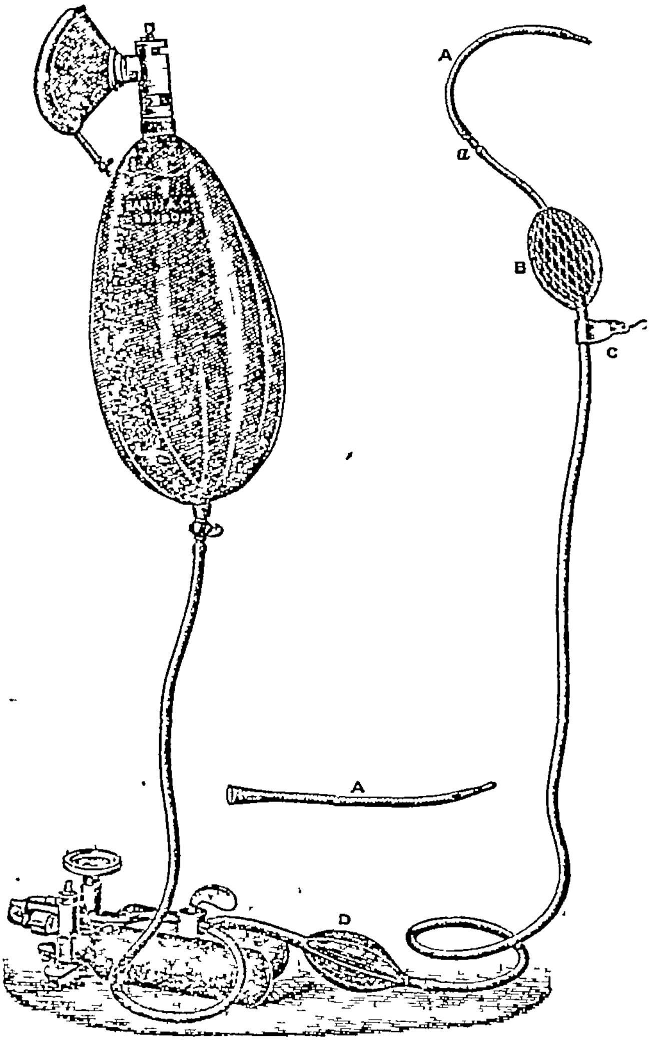
In three of the cases the kidney was apparently dislocated by definite injury. In most of them there were firm adhesions between the kidney and its outer fibro-fatty capsule.

Clifton, Bristol.

FURTHER NOTES ON THE USE OF THE NASO-PHARYNGEAL TUBE FOR PROLONGED NITROUS OXIDE ANÆSTHESIA.

BY HARVEY HILLIARD, M.R.C.S. ENG., L.R.C.P. LOND.,
ASSISTANT INSTRUCTOR OF ANÆSTHETICS AT THE LONDON HOSPITAL AND THE ROYAL DENTAL HOSPITAL; LATE REGISTRAR IN CHARGE OF THE CEYLON MEDICAL COLLEGE, ETC.

ON May 7th, 1898, p. 1244, I published in THE LANCET a short paper on a method of prolonging nitrous oxide anæsthesia for dental operations by administering the gas through a naso-pharyngeal tube apparatus which I had devised Further observations of this method were prevented by an absence of two years in Ceylon, which deprived me of the opportunity of bringing it more prominently to the notice of the profession, but since that time the more extended employment of the apparatus then described, in all kinds of cases in dental surgery, has convinced me that the use of ether, with all its objections, need practically never be resorted to, and this fact will assure the welcome of this method not only by dental surgeons and anæsthetists but in even greater measure by the public when it becomes more widely known, for all are agreed that N_2O is the most perfect anæsthetic at our disposal. This, then, must be my excuse for referring again to the subject and it renders further apology needless.



The apparatus, which has been most carefully made to my design by Messrs. Barth and Co., consists of a two-way stopcock, the inlet tube of which screws into the union connecting the gas cylinders in such a manner that the whole stopcock lies between them and is thus out of the way; the tap of the stopcock is an elongated broad arm so that it can be easily turned by the foot. From the stopcock chamber lead two tubes of exit, and the tap is so arranged that when it is turned on to either of the two exit tubes the arm lies over that tube through which the gas will flow when liberated from the cylinders by means of the ordinary foot-key. The whole gas-supply can thus be entirely controlled by the administrator's foot. The exit tubes, like the other parts of the stopcock, are made of brass, are placed at an angle, and are an inch long, with bulbous ends so that the rubber tubing can be easily slipped over them; to the left hand one, which is of the same calibre as the union connecting the cylinders, is attached a Hewitt's gas-inhaling apparatus, to the other—the right-hand one—which is marked with the letter "N" and has a very fine calibre in order to reduce greatly the rapidity of the gas flow, is attached the other connexions of the nasal tube—viz., a small stout rubber "expansion bag" (vide diagram D) which is connected at one end with the stopcock exit, the other extremity being continued by tubing to a thinner and smaller rubber bag, B, also netted and which I have called the "pressure bag," as it shows the degree of pressure at which the gas is being supplied; it is fixed to the headpiece of the dental chair by a safety-pin hook, C. This bag is continued as a small rubber tube inclosed in a spiral of steel wire to prevent kinking, and terminates in a conical vulcanite nozzle *a*, fitting into the funnel-shaped extremity of the naso-pharyngeal tube proper, A. These tubes are made for me by Messrs. Stevens and Sons in three sizes—corresponding to numbers 7, 8, and 9 male English catheters—and consist of soft silk gum-elastic; they are six inches in length with the distal end made "*à boule*" and solid up to the orifice, which is situated half an inch from the point, the proximal end being expanded to receive the conical vulcanite attachment of the tubing.

Having occasionally experienced difficulty during a prolonged administration with the original apparatus, owing to the intermittent and irregular evaporation of the fluid nitrous oxide from the cylinders, which was not sufficiently compensated by the expansion bag provided to prevent it and which became in consequence over-distended, I found it necessary to make certain alterations in the construction of the apparatus, thereby eliminating these evils and making the administration more easy. To prevent too rapid a flow of gas the right-hand nozzle of the stopcock—to which the rest of the apparatus is attached—has been made with a very much finer orifice; this allows a much more delicate adjustment of the gas-supply and prevents those sudden escapes from the cylinders which not infrequently arise owing to a partial occlusion of the valve from frost suddenly giving way. In addition, also, the "expansion bag" is now made of half the thickness and double the capacity, which much more effectually regulates the flow by converting an intermittent stream into a continuous one; this bag is inclosed in a net of stout silk to prevent over-expansion, any tendency to which after maximum distension is at once seen in the pressure bag. This pressure bag is small and is made of thin rubber which easily stretches under slight pressure, it is inclosed in a loose net. Its object is to show, approximately, under what pressure the gas is being supplied and to act as a danger signal when this becomes too great, it also enhances the action of the expansion bag in regulating the flow of gas; for this reason it is placed well in view, next to the hook which fixes the apparatus to the headpiece of the dental chair; from it comes off the small rubber tube which terminates in a vulcanite nozzle made to fit into the naso-pharyngeal tube and which is protected from kinking or compression by a spiral coil of steel wire.

With these modifications I have been able to obtain much quieter and more satisfactory anæsthesia, without that tendency to over-dosage which was one of the disadvantages of the first apparatus. Now, too, since certain dental surgeons have become accustomed to its use they have undertaken more extensive operations, have worked with greater calmness and precision, and in consequence the periods of anæsthesia have been necessarily prolonged, the maximum hitherto being seven and a half minutes. The average anæsthesia reckoned from the last 100 consecutive cases of which I have made notes is 2·75 minutes; these cases were selected for treatment with the tube on account of the necessary operation being unusually extensive or of great difficulty.

Some objections have been raised to the employment of the naso-pharyngeal tube on the following grounds: 1. That it is inadmissible in cases of nasal obstruction. As a theoretical objection this is valid enough, but practically it is very trivial, for in over 300 cases I have not met with a single case in which I could not rapidly pass my tube down one or other nostril; cases of complete nasal obstruction are extremely rare. 2. That the passage of the tube gives rise to hæmorrhage. In the 300 cases before-mentioned I have not in a single instance met with anything approaching troublesome bleeding; in six cases only among the last 100 there was slight oozing for a few minutes, and these cases suffered from hypertrophied and very vascular turbinal mucosa, which is not a common condition and is no contra-indication to the careful passage of a soft gum elastic tube no larger than a No. 9 catheter. 3. That the method cannot be used in cases of adenoids. When I had less experience of these cases I believed this to be true and therefore I did not employ my apparatus in children suffering from adenoids, but latterly, to meet objectors, I have been on the look-out for them and have not met with difficulty or unpleasant after-effects. A little blood must be expected, but as a rule the growths are soft and not very vascular and are easily pushed aside by the tube. One word of caution, however, is necessary with regard to adenoid cases—these are almost always in children; children at any time are rapidly anæsthetised with N_2O and show jactitation early when no air is administered with the gas, but, owing to the obstructed nasal respiration and the relatively small mouth, so little air is inspired in proportion to the anæsthetic, when administered continuously with the tube, that there is a danger of over-dosage. The greatest care and attention are therefore imperative in treating these cases and the gas should be allowed to flow into the pharynx as gently as possible; indeed, in all cases of impeded nasal respiration and in the anæmic the difficulty is not to keep the patient under but to give sufficiently little. 4. That the method is septic because the nasal tubes may convey disease germs from one case to another. This may occur in the hands of those ignorant of the elements of aseptic surgery, in spite of the fact that the tubes are easily sterilised and that furthermore their interior is never soiled, since the full stream of gas emerging from them effectually prevents any foreign matter entering; it is as easy to convey sepsis by an ordinary facepiece or a dental forceps.

I have here quoted the objections that have been raised by theorists and those who have had little or no experience of the method, but on the other hand, operators have never complained that the apparatus has impeded their manipulations or that their time has been taken up assisting the anæsthetist by having to use a mason's gag—a duty for which he is entirely responsible. Indeed, with this apparatus not only can the administrator easily perform all his legitimate duties but he can further aid the operator by helping to sponge out the mouth, for both hands are not occupied in managing the apparatus. Some other advantages of this apparatus over other methods for prolonging N_2O anæsthesia are that it leaves the mouth entirely unobstructed to the operator, whereas the nosepiece considerably hampers his manipulations in the front of the mouth by pressing upon the upper lip. The disadvantage of any form of mouth tube is obvious in this connexion. The tube is easily kept in place by the thumb of either hand while supporting the head, and the prop or mason's gag can be manipulated with the greatest ease without preventing the anæsthetist giving his assistance in sponging. With the nosepiece, on the other hand, it is sometimes a matter of difficulty to keep the apparatus in place; while one hand is occupied in doing so, the other is necessary to work the air valve. Again, with the nosepiece the success of the anæsthesia largely depends upon whether or not the patient is a persistent mouth-breather, whereas with the nasal tube the ordinary respiratory rhythm is not interfered with and the patient is bound to get the gas whether he breathes through the mouth or through the nose, since the gas is supplied in the naso-pharyngeal space, the stream being directed downwards upon the upper opening of the larynx.

In only one case have I been unable to maintain the anæsthesia sufficiently to keep the patient quiet for longer than one minute. In this case the patient was a very neurotic girl with a highly arched palate and very little naso-pharyngeal space. She had had gas on three previous occasions and each time she screamed and fought, the anæsthesia being too short to permit of the operation being accomplished. Anæsthesia was obtained with the tube, but having pushed the gas to its limit of safety, with resulting extreme cyanosis, I was obliged to stop the administration for a few moments, during which the patient recovered so quickly that before sufficient gas could again be administered she fought so much that I was forced to discontinue the administration altogether.

In the vast majority of cases one could easily give a lethal dose with this apparatus by closing the patient's nostrils with the fingers. I was obliged to resort to this practice in the case of an alcoholic patient who stated that on a previous occasion an unsuccessful attempt had been made to anæsthetise him; he had taken a glass of whisky on his way to the dentist, but with the tube and compression of the nares anæsthesia was easily maintained for one and half minutes; there was some rigidity throughout.

It is needless to multiply cases here; the average anæsthesia in 200 consecutive administrations is sufficient to show the capabilities of the method. They were selected on account of the operation being likely to prove unusually protracted. But even in an ordinary case it is an obvious advantage to the surgeon to be able to operate with deliberation, in the full confidence that there is no probability of the patient coming round before he has finished his manipulations. To the patient the advantage is two-fold: first, he is spared the necessity for either several distinct operations on several distinct days or the alternative of ether anæsthesia, and secondly, the risk of damage to the mouth from a hurried operation.

With regard to the administration itself, the gas is turned on to the ordinary apparatus and the administration is conducted in the usual way to the stage of light anæsthesia; with a full bag the facepiece is then momentarily removed and the tube is passed during an expiration; by so doing the patient inhales no air during this proceeding. It is important not to pass the tube until the patient is unconscious, for otherwise its presence in the nares causes lacrymation, phonation, or other signs of irritation and excitement. When the point of the tube is felt to impinge on the posterior pharyngeal wall the facepiece is re-applied over it, the two-way stopcock is turned so that the gas now flows through the nasal tube, and the administration is continued to full anæsthesia by means of both apparatus in order to see that everything is working properly. Before passage of the tube its point should be slightly bent downwards so that it is the more easily directed along the floor of the inferior meatus of the nose; unless this is done it is not difficult to pass it into the middle meatus, where obstruction is sure to be met with and bleeding is likely to arise. When its point is felt to impinge on the posterior pharyngeal wall the tube should be passed no further for fear of inflating the œsophagus and of causing swallowing movements or even vomiting.

The best and safest position in which to place the patient is sitting straight up in the chair with the head erect—i.e., tilted neither forwards nor backwards—in this posture there is no embarrassment of the respiration from stretching of the muscles of the neck and it is the best position for the surgeon when operating upon the lower jaw, while the head can always easily be tilted back after anæsthesia is complete for operations upon the upper jaw. What is far more important, however, is the fact that the bleeding caused by the operation does not gravitate backwards into the pharynx with the attendant risk of being inhaled and causing asphyxia, but it collects in the floor of the mouth whence it is removed easily with a sponge. The advantage of this posture is felt with those patients who salivate freely under gas and in whom troublesome coughing or retching is caused during induction by the saliva trickling backwards into the pharynx.

In cases requiring prolonged nitrous oxide anæsthesia it is more important than usual to have the bladder empty before the operation and the patient should abstain from food for at least three hours before the time fixed for operation, as subsequent nausea is less uncommon than after an ordinary administration. Loose clothing is imperative.

Since I first introduced this apparatus in 1893 I have been able in my own practice to make good the claim which I then made for it—viz., that it would render the employment of ether in dental surgery unnecessary; that owing to its small bulk and great portability it is more convenient and economical, as regards the quantity of N_2O used, than any other apparatus employed with the same object; and, finally, that it is free from risk of damage to the nose, naso-pharynx, and mouth, and is without danger to the patient.

Wilton place, S.W.

ON THE TREATMENT OF INCIPIENT BRONCHO-PNEUMONIA IN INFANTS.

BY THEODORE ZANGGER, M.D.,

LATE ASSISTANT PHYSICIAN, UNIVERSITY HOSPITAL, ZÜRICH.

INFANTILE pneumonia is a serious condition which deserves special attention, as in very young or ill-nourished children, but especially in cases debilitated by previous illness, it often proves fatal. But apart from the fact that the child's life is in jeopardy, in distinction from lobar pneumonia which generally terminates within a fortnight, broncho-pneumonia drags on for three, four, or six weeks and more. The continual fever has a detrimental effect on all the tissues, but especially on the heart, and the result is that convalescence is often complicated by anæmia, intractable dyspepsia, &c., and the danger of incomplete restitution of the tissue of the lung or incipient phthisis must not be underrated.

Any means to shorten the disease must be seriously considered by the physician. The question is: Have we any means at our command to arrest the disease at the outset or at least to shorten materially the duration of the pneumonia? I believe that I am in a position to reply in the affirmative. It is obvious that the evidence adduced must rest on a firm basis of indubitable clinical facts and that these must receive a careful and logical consideration. The treatment referred to is not medicinal from a pharmaceutist's point of view but belongs to the domain of hydro-therapeutics in a simple form, so as to be available even in country practice. I am anxious that none of my professional colleagues should disregard it merely on the ground of its simplicity or because he has already made use of similar but not identical measures of treatment. My method of treatment claims no special originality; it is the result of the theoretical and practical study of hydro-therapeutics extended over a number of years. My evidence is partly of a negative and partly of a positive kind. Let me start with the former.

Pneumonia is most often met with as a complication of two infantile diseases—viz., whooping-cough and measles. No one will contradict the statement that the mortality of these two diseases is greatly dependent on the question whether pneumonia ensues or can be warded off. Voit gives the mortality of whooping-cough at 25 per cent. in children under one year of age and at 4·8 per cent. in those between one year and five years. Let us compare with this statement the fact that 6 46 per cent. of 4181 cases of whooping-cough were complicated with capillary bronchitis (Szabó).[1] One can treat measles and whooping-cough exclusively on hydro-therapeutic principles. The result is decidedly better than if one treats the patient only medicinally and avoids making use of hydriatric procedures. But the best results are doubtless obtained by a combination of these two treatments and I in no wise wish to underrate proper drug treatment. The proper use of hydro-therapy in both these diseases tends to ward off complications In about 120 cases of whooping-cough in children aged from three weeks upwards who have been under my care till they were cured I have not seen a single case of pneumonia develop, consequently the mortality was *nil*. Five patients had already more or less severe broncho-pneumonia when they entered on my treatment; they all recovered within six weeks.[2] The best results were obtained by combining hydro-therapeutic measures with medicinal treatment; in my cases hydrochlorate of quinine or euchinine rendered me better service than bromoform.[3] My cases of measles, numbering about 150, I have not yet revised and published. Here also I have no fatal case to record, though of course I do not pretend that the mortality must be *nil* under a line of treatment which has given me such favourable results even partly under unfavourable hygienic surroundings and deficient nursing. Pneumonia as a complication I have only observed in half a dozen cases, one of which I will refer to in detail. The duration of the pneumonia never exceeded one week, nor that of the total convalescence three weeks. I will now give some short notes on cases observed within the last half-year. They refer partly to pneumonia checked at the onset and partly to the successful treatment of fully-developed pneumonia. To do more than mention my other cases thus treated would be a useless repetition.

CASE 1.—This patient was four years old and belonged to a poor family living under unhygienic conditions. She was taken ill with high fever on Jan. 21st, 1902. On the following day a rash rapidly developed and spread over the body. I diagnosed measles. From the outset the child seemed exceedingly ill, the rash was very intense, the conjunctivitis and pharyngitis were very severe, and the cough was exceedingly troublesome and was hardly relieved by wet packs for the chest and the bronchitis kettle kept beside the bed. On the 26th (the fifth day) the temperature, which had gone down, rose again to 103° F. and the cough continued to be very irritating. The child would scarcely move and was slightly somnolent; the number of heart beats was increased by one-third and the number of respirations also. There were signs of deficient breathing with small non-crepitant râles and dulness on percussion over the lower part of the right lung posteriorly. Incipient pneumonia was diagnosed and a "half bath" (*Halb-bad*) with friction was ordered and applied for four minutes. The temperature of the bath was 30° C. (86° F.) at first and was then decreased slowly to 24° C. (76° F.). It was to be repeated within 12 hours if the temperature remained over 103°. The next morning the child looked quite different, so that no second bath was ordered. She was brighter and more lively and asked for solid food which, however, was not given. Her temperature was 37·5° C. (99·5° F.) and remained normal. The lung symptoms persisted for a few days; diffuse bronchitis with small râles was recognisable, but these also rapidly disappeared on the application of cross packs (*Kreuz-binden*) No medicine was prescribed. Complete recovery ensued and the patient was pronounced quite well on the 30th.

CASE 2.—This patient was a delicate boy three years old, one of a working-class family of six. He fell ill with measles, as the mother reported, on Jan. 26th, 1902, and was treated by the parents themselves. As the fever continued they called me in on Feb. 1st. I found the spotted condition of skin seen after measles. The temperature varied from 101·6° to 102 2° F. There was pneumonic infiltration into the base of the left lung and the boy looked very ill. Baths were ordered as above. After three baths of from 86° to 76° of four minutes' duration, repeated only every 24 hours as the boy was weak, the fever abated, and the lung symptoms disappeared a few days afterwards. Recovery was complete on the 10th; a quinine tonic, however, was prescribed. I may here mention that the vin de Vial has among a score of other tonics given me excellent results in infantile diseases; during convalescence it may be taken in half teaspoonful to teaspoonful doses three times a day.

CASE 3.—This patient was aged five years. At the age of four and a half months in the course of protracted eczema of the face she developed diphtheria of the skin of the face and this rapidly spread to the conjunctiva where diphtheritic membranes formed. An antitoxin injection saved the cornea and probably also the life of the child. Since then she had been weakly, though a child of very healthy parents, and had been susceptible to cold and attacks of tonsillitis. She was taken ill on Jan. 2nd, 1902, with fever and a cough. As the temperature continued to run up from 101° to 104° F. I was called in on the 5th. The child had very severe and extensive bronchitis and capillary bronchitis, but so far no symptoms of infiltration of the lungs. Notwithstanding cool packs from under the arms to the ankles (*dreiviertel Packungen*) the state of the child became rapidly worse, the respiration rose to 40 per minute, and the pulse-rate to 160; there were dilatation of the right heart to the right of the sternum and evidence of commencing cyanosis associated with a temperature varying from 103 6° to 104 6°. Infiltration of the base of the right lung gave the clue to these symptoms, the diffuse bronchitis having increased in severity. The case threatened to be serious. The parents agreed to a tepid bath of from 28° to 26° C. (82° to 78° F.) which was applied for seven minutes with rubbing. The condition of the patient greatly improved within 12 hours; the temperature was 100°

---

[1] Thus a high percentage of all the deaths must be due to capillary bronchitis and pneumonia.

[2] I had not in those days begun to treat pneumonia with tepid baths and in the latter years I have not come across a case of whooping-cough complicated with pneumonia.

[3] Zur Therapie des Keuchhustens, Correspondenzblatt für Schweizer Aerzte, 1901, No. xii.

the next morning and declined to normal within 24 hours and without a second bath being given. The symptoms of infiltration of the lung were discernible for four days (crepitant râles and dull percussion note); the symptoms of bronchitis disappeared with marvellous rapidity under the application of cross packs. The patient's recovery was complete on the 18th and she was seen in full health in April.

CASE 4.—This patient was my own daughter, a healthy infant one year old. She was teething and had been suffering from slight cough for 10 days. She was taken ill with a rather severe attack of varicella on April 20th, 1902, with hundreds of vesicles all over the body, in the mouth, on the soft and hard palate, and on the conjunctivæ. The temperature from the 20th to the 22nd ranged from 100° to 101° F. On the 23rd she coughed more, seemed very ill, was very apathetic and drowsy, and took very little food. Baths of from 95° to 93° with bran had been given so far morning and night, each of from five to 10 minutes' duration. This is my usual treatment of varicella, the excessive irritation of the skin soon subsides under it. On the 24th the child's temperature rose to 103° and breathing was impeded, the cough was painful, and the pulse-rate was high. Professor O. Wyss, who was called in in consultation, diagnosed incipient pneumonia in the left lung, otherwise diffuse bronchitis. We agreed to give a bath of from 94° to 86° continuously for five minutes, Professor Wyss being averse to lower temperatures. On the 25th it was noted that the child had a very disturbed night. Symptoms of infiltration of the lung were clearly defined, there were crepitant râles over the left lung and dulness on percussion. The child was very weak, could scarcely sit up, coughed a great deal, and was very drowsy. The temperature rose to 103·6° in the evening. I gave the little patient a bath at from 86° to 79° continued for six minutes but without friction in order not to irritate the vesicles which were drying up or had dried up. The child had a good night with less cough, her temperature on the 26th was 99·6° in the morning and 98·6° in the evening, after which it continued normal. The child now sat up again and her pulse-rate and respiration rate were normal. On the 27th crepitant râles over the base of the left lung and dulness on percussion were very distinct. The child looked very pale but was lively. The bronchitis was improving. Baths of from 95° to 90° were resumed morning and night for from three to five minutes.[4] On the 28th the crepitant râles had disappeared, the percussion note was almost equal on both sides, there was very little bronchitis, the child's temperature was normal, and she had very little cough. Convalescence was prolonged owing to a very acute attack of follicular tonsillitis a week later, but she was quite well on May 18th.

I must mention that I have here only referred to cases where no medicines were given. I have done so in order to prove that the hydro-therapeutic procedures alone cut short the duration of the pneumonia. Even if these simple methods sufficed in such simple cases—and they could scarcely do better on any other treatment—yet drug treatment in combination with this "water cure" (*sit venia verbo*) will certainly be desirable in somewhat severe or prolonged cases. However, it is very much to be regretted that many physicians resort to the use of these baths only in the second or third week of pneumonia when the case is becoming more and more serious. Why use them only as a last resource, and *why not in the incipient stage?* Brand obtained his remarkably low mortality of 3·5 per cent. in the treatment of typhoid fever cases when they were treated with tepid baths from the onset.

Of course these baths can be varied in duration and temperature; packs have not given me as good results. The experienced hydro-therapeutist will vary the procedures according to the physique of the patient, the age, the severity of the symptoms, the complications, &c. For first trials I prefer recommending something simple and well defined, as a wrong technique may result in harm to the patient and also reflect detrimentally on the method of treatment and the medical practitioner as well. It is advisable for the latter personally to supervise the first bath at least; for feeble infants a stimulant is a necessary preliminary.

Let me resume. At the very first onset of pneumonic symptoms (high temperature, diminished resonance, small non-crepitant or crepitant râles, apathy, increased rates of heart beat and respiration) I give a bath of 86° F. for two minutes and then slowly reduce the temperature of the bath by adding cold water for from two to three minutes till a temperature of 76° is reached. I rub the body of the patient with a sponge or cloth or the hand to promote reaction of the skin and reduction of the body heat. The bath water need not, and in cases of feeble children should not, quite cover the body but the water can be sponged on the chest, the patient lying in the arms of an attendant. If definite pneumonic symptoms be present the bath may have to be repeated at intervals of from eight to 24 hours. The cross packs (*Kreuzbinden*) relieve the symptoms of bronchitis. I use them extensively in incipient phthisis, but they give excellent results, and naturally prompter ones, in uncomplicated simple bronchitis. They are applied in the following way. A linen bandage about one and a half inches broad for infants and five inches for adults, and from two to three yards long, is placed in cold water (from 54° to 66°), is well wrung out, and is applied to the chest thus—(1) beginning under the right axilla, passing over the left clavicle and round the chest back to the right axilla; (2) from here round the chest horizontally; (3) from the right axilla to the left and over the back and the left clavicle to the front (or left axilla). This bandage is covered in the same way with a thick single, or thin double, flannel bandage perhaps half an inch broader. This "pack" is applied at night and left till the morning; on removing it the chest must be well rubbed with a cold, wet towel and then rubbed dry.

I shall be glad if this method of treatment is favourably received and tried by my colleagues. These tepid baths are far superior to the chest packs so universally recommended. The latter harass the child, disturb its sleep if changed every one or two hours, trouble the attendants, and if continued day after day they tend to weaken the child, especially if not alternated with cold, wet friction. The results of the tepid bath, which have been best studied in cases of typhoid fever, do not merely rest on the reduction of body heat; it is not merely palliative but curative. The capillaries of the skin, that vast reservoir, are filled with blood; this temporarily relieves congested internal organs and improves their circulation; the action of the heart as well as that of the most important nerve centres (*imprimis* the vaso-motor centre) are stimulated by reflex action, defecation is promoted, and especially diuresis, thus causing the elimination of toxic substances.

Zürich.

SOME EXPERIMENTS ON THE PRECIPITINS.

BY ALDO CASTELLANI, M.D.

FLORENCE.

(From the Bacteriological Department, Jenner Institute of Preventive Medicine.)

WE are indebted to Bordet and to Wasserman for the first researches on the precipitins—a group of bodies which are every day acquiring greater importance on account of the many practical applications of which they are susceptible. Bordet observed that when a rabbit received several injections of cow's milk its blood acquired certain special properties. Thus the blood serum of the treated rabbit on addition to diluted milk produced a precipitate in the milk. This precipitate did not occur on the addition of a normal rabbit's blood to milk. Wasserman not only confirmed this observation but clearly demonstrated that in this respect every species of animal has a milk which acts in a specific manner. For instance, the serum of rabbits immunised with cow's milk produces the above reaction in fresh cow's milk, but does not do so in goat's milk or in human milk, &c. A fresh impulse was given to these researches by Bordet himself in his study of the precipitins of the blood. The French author, following up the work of the Italian observer Belfanti, has already shown that on injecting animals with the blood of another species the serum of the treated animals developed specific lysins and agglutinins for the erythrocytes of the blood of the species employed. And Bordet, continuing his experiments, observed that if animals were injected simply with the serum of another species [illegible] precipitins were likewise developed in the serum of the treated animals. For example, the blood of a rabbit which had been treated with the dog's serum produced a precipitate in, and only in, normal dog's serum. These researches were extended in various directions—e.g., by Wasserman, Uhlenhuth, Nuttall, and Schütze. And upon the results obtained a method was based for the special identification of human blood. For this purpose repeated doses of human serum were given to a rabbit. After a certain time it was found that the serum of the treated rabbits had acquired definite specific properties as regards human blood, and was capable of producing a precipitate not only in fresh human serum but likewise in very dilute serum solutions obtained by redissolving dried human blood-stains several weeks old. The serum of the rabbits, however, did not produce a precipitate in any other serum, with the one exception of the monkey's, in which a slight positive reaction was obtained. This method has already been applied in medico-legal investigations with good results (Ferrai, Ogier, Stockis). Another interesting fact may be noted here—viz, that the blood of animals immunised with human serum causes also a precipitate in albuminous urines (Stern) as well as in ascitic and hydrocele fluid (Schütze, Dieudonné).

---

[4] No cross packs were ordered in this case owing to the varicella as they would naturally macerate the skin and irritate the vesicles and perhaps also promote secondary infection of these little ulcers.

Farmen likewise has applied this biological test to semen. Rabbits injected with the sperma of different species of animals developed specific precipitins in their blood. Thus, the serum of a rabbit which had been immunised with dog-sperma produced a precipitate in a salt emulsion of dog sperma, but not in emulsions of sperma from other sources. Schütze has recently published[1] an important paper on the differentiation of different albuminoid preparations by means of similar biological tests; and closely connected with the above observations are the interesting researches of Kraus upon the specific precipitates that occur in *filtered* cultures of micro-organisms on the addition of the serum of animals previously immunised with bacterial cultures. Kraus showed that the serum of a typhoid-immunised animal induced a precipitate in a clear filtrate of a culture of the typhoid bacillus, but that it was impossible to obtain a precipitate by adding the serum of animals immunised with other bacteria.

The first experiments which I have made were with reference to the specific precipitins which might be obtained by immunising animals with different kinds of proteid preparations, and they were undertaken with the view of obtaining some preliminary data for the special research I had in view. These experiments were carried out with two albuminoid preparations known commercially as somatose and "roborat," the latter a vegetable proteid derivative.

A strong solution of somatose in physiological salt solution was used for injection into rabbits. A subcutaneous injection of five cubic centimetres was made and this was repeated several times. Injections of "roborat" were made in a similar fashion. The "roborat" was previously dissolved in hot water and filtered before use. The rabbits did not suffer in any way from the injection of these preparations nor did they lose weight. At the end of two weeks' treatment the animals which had received "roborat" gave evidence of a distinct formation of precipitins in their blood. A few drops of their serum produced a distinct precipitate in a fresh solution of "roborat" The reaction was best obtained by keeping the tubes for some hours at blood heat. The reaction, on the other hand, did not occur on adding the serum of the treated animal to a solution of somatose. As regards the rabbits which had been treated with somatose the formation of a specific precipitin was not so clearly marked, but still, although after a longer period of time, it was possible to produce a slight precipitate with their serum in a solution of somatose, whilst none occurred in a solution of "roborat." These experiments demonstrate once more the possibility of obtaining specific biological, in contradiction to purely chemical, tests for proteid bodies whether these be of animal or vegetable origin. Many valuable extensions might and are being made in this direction.

The subsequent experiments which I made were with *special reference to the precipitins produced by the serum* of animals immunised with living cultures of bacteria. These experiments were performed with the bacillus typhosus, staphylococcus pyogenes aureus, and two varieties of bacillus coli, designated by the numbers I. and II. A series of rabbits were immunised by the subcutaneous inoculation of living broth cultures of the above organisms. The blood of the treated animals very quickly acquired marked agglutinating properties with regard to the respective organisms employed. I may point out in this connexion that the typhoid serum, in addition to agglutinating very markedly the bacillus typhosus in a dilution of 1 in 10,000, also agglutinated to a certain degree (1 in 200) the Bacillus coli II., although it did not agglutinate the Colon bacillus, strain I. The possibility of some typhoid sera agglutinating certain strains of the colon bacillus has already been experimentally demonstrated by Iatta.

The following are the details of some of my experiments:—

EXPERIMENT I.—A broth culture of typhoid four weeks old was passed through a Berkefeld filter. The sterility of the filtrate was controlled by microscopic examination and by incubation of the filtrate for 24 hours at blood heat. To each of three test tubes five cubic centimetres of the clear filtrate were added and to each of these the serum of a rabbit immunised with typhoid bacilli was added in the following proportions: one cubic centimetre, half a cubic centimetre, and one-twentieth of a cubic centimetre. The tubes were then placed for 12 hours in the incubator at blood heat. At the end of that period the first and second tubes contained a marked precipitate whilst the third tube showed a very slight one.

EXPERIMENT II.—The same fluid was tested as in Experiment I.—viz., a filtered culture of the typhoid organism. To a series of test-tubes containing five cubic centimetres of the filtrate were added two cubic centimetres, one cubic centimetre, half a cubic centimetre, and one-twentieth of a cubic centimetre of serum taken from a rabbit immunised with Bacillus coli I. To a second series of tubes, containing the typhoid filtrate, similar quantities of serum obtained from a rabbit immunised with Bacillus coli II. were added. No precipitate occurred in any of the tubes after 12 hours' incubation at blood heat.

EXPERIMENT III.—Four weeks' old broth cultures of the first strain of the colon bacillus were filtered and added to three series of test tubes. To the first series were added varying quantities (one cubic centimetre to one-twentieth of a cubic centimetre) of the first colon serum, to the second graduated quantities of the second colon serum, and to the third typhoid serum. The result was that only the first series gave precipitates.

EXPERIMENT IV.—The filtrate from an old broth culture of Colon bacillus II. was added to the three test tubes, to each of which was likewise added half a cubic centimetre of Colon serum II., Colon serum I., and typhoid serum respectively. After 12 hours at blood heat the first tube contained a marked precipitate, the second was quite clear, and the third (typhoid serum) contained a very slight precipitate. As I have already remarked, the typhoid serum had also a certain agglutinating power on Colon bacillus II. The serum of Colon bacillus I., on the other hand, had no agglutinating power on Colon bacillus II.

EXPERIMENT V.—To the filtrate of an old broth culture of staphylococcus pyogenes aureus were added varying quantities of the serum of a rabbit which had been immunised with living broth cultures of the same organism. The addition of one tenth of a cubic centimetre of the staphylococcus serum was sufficient to produce a distinct precipitate in the filtered culture of the same organism, but the results were negative with colon and typhoid serum.

EXPERIMENT VI.—A rabbit was simultaneously immunised with the typhoid bacillus and with the colon bacillus by injecting subcutaneously living broth cultures of the typhoid and the colon bacillus. Two weeks subsequently the blood showed very strong agglutinating properties on both of these organisms, whilst at the same time the formation of agglutinins had been accompanied by the production of precipitins. The serum produced not only an agglutination but a precipitation in filtered cultures of the typhoid and of the colon bacillus.

The above experiments were typical of the results obtained and are confirmatory of the observations made by Kraus, and, in my opinion, they point to the existence of a certain correlation between the agglutinins and precipitins. This correlation appears to me to be evident from the following facts. The serum of an animal, for instance, which has been immunised with the typhoid bacillus develops along with its acquired power of agglutination the property of producing a precipitate in the filtrate from typhoid cultures.

---

[1] Zeitschrift fur Hygiene, vol. xxxviii.

The agglutination is a specific phenomenon, but this specificity is only relative inasmuch as a typhoid serum may likewise exhibit a certain degree of agglutinating power on some strains of the colon organism. Similarly I have found that the precipitins are not absolutely specific. A typhoid serum which agglutinates a certain strain of the colon bacillus will at the same time produce a slight precipitate in a filtered culture of the same colon organism. Finally, I have observed that if an animal be immunised with different bacteria at the same time a poly-agglutinating serum results, in the same way that a serum results which will produce a precipitate in filtered cultures of the several organisms used for immunisation. This had already been observed by Wolff as regards a poly agglutinating serum.

I next proceeded to study the precipitins which might be produced by the serum of animals that had been treated with *filtered* broth cultures of bacteria.

Kraus, experimenting in this direction with the diphtheria bacillus, came to entirely negative results, and was led to the conclusion that there is no formation of precipitins in the serum of animals treated with germ free filtered cultures. I may say at once that experimenting like Kraus with the diphtheria bacillus I came to a similar conclusion But the results are of a different character if the experiments are extended to other bacteria. For example, cultures of the typhoid bacillus, colon bacillus, and staphylococcus aureus were freed from the organisms by filtration through a Berkefeld filter and the filtrates were injected into rabbits. In the blood of all the treated animals it was easy, after a certain time, to detect the formation of specific precipitins, as will be seen from the following experiments.

EXPERIMENT I.—The filtrate from an *old* broth culture of the typhoid bacillus was added to three series of test tubes. To the first series were added varying quantities of the serum of a rabbit (from one cubic centimetre to one twentieth of a cubic centimetre) which had been treated with filtered cultures of the typhoid bacillus. To the second series were added the same quantities of serum taken from an animal treated with filtrates of cultures of the colon bacillus, and to the third the serum of a rabbit which had received filtered cultures of the staphylococcus aureus. After being kept for 20 hours at blood heat two tubes of the first series contained distinct precipitates—viz., those to which one cubic centimetre and half a cubic centimetre of the typhoid serum had been added. The test tubes in the second and third series, on the other hand, remained perfectly clear

EXPERIMENT II.—An *old* broth culture of staphylococcus aureus was passed through a Berkefeld filter, and the filtrate added from a rabbit treated with staphylococcus filtrate, to a second half a cubic centimetre of serum from a rabbit treated with typhoid filtrate, and to a third half a cubic centimetre of serum from an animal treated with colon filtrate. At the end of 12 hours a precipitate occurred in the first tube and not in the other

EXPERIMENT III.—To the filtrate of diphtheria cultures I added in varying quantities the serum of a horse immunised in the usual manner with diphtheria toxin. I was, however, not able to detect any precipitin, although the tubes were kept at blood heat for 48 hours

The above observations show that on immunising animals with bacterial free filtrates of cultures of the typhoid bacillus, colon bacillus, and staphylococcus aureus it is possible to induce a formation of precipitins in their blood. The results were negative in the case of filtered cultures of the diphtheria bacillus. This fact, is in my opinion, an additional argument in favour of the intimate relation existing between the agglutinins and precipitins. For if we treat an animal with filtered diphtheria cultures we do not induce in its blood a formation of agglutinins (or only very slightly), but if we treat an animal, e.g., with filtered typhoid cultures, the blood will acquire a marked agglutinating power, though not so strong as if we had carried out the immunisation of the animal with unfiltered cultures.

A final series of experiments was made in order to determine whether precipitins were formed in the serum of animals that had been treated with *dialysed* cultures of bacteria. For this purpose typhoid cultures were taken (45 days old) and dialysed by means of a Martin gelatin filter The dialysates were injected several times into two rabbits five cubic centimetres at a time being inoculated subcutaneously 12 days after the first injection the agglutinating power of the blood of the animals was tested and it was found that it had acquired distinct agglutinating properties, a distinct agglutination of typhoid bacilli being produced by a dilution of 1 in 500. This confirms the observation made by Macfadyen that it is possible to induce a formation of agglutinins by treating animals with dialysed cultures I tested the blood at the same time for the formation of precipitates, using as test material old filtered cultures of the typhoid organism. The results were positive. The serum of the animals treated with the dialysed cultures produced in doses of 0·5 and 0·25 cubic centimetre a precipitate in the filtered typhoid broth. The serum did not produce any precipitate in filtered cultures of staphylococcus aureus or the colon bacillus My experiments, therefore, lead me to the conclusion that it is possible to induce the formation of precipitins as well as agglutinins by injecting dialysed cultures. My experiments lay no claim to completeness and it is my intention to continue and to expand them. Thus it would be interesting to test whether the serum of typhoid fever patients causes a precipitate in filtered typhoid cultures.

The experiments which I have made point to the following conclusions 1 The blood serum of animals treated with different preparations of natural albumins contains specific precipitins for the albumins. 2. The blood serum of animals treated with unfiltered bacterial cultures produces a precipitate in filtered cultures of the organisms in question. 3. The serum of animals treated with *filtered* cultures of bacteria likewise develops specific precipitins which produce precipitates in the filtered cultures of the same bacteria. 4 An exception was in the case of diphtheria cultures, the injection of which did not lead in my hands to the production of precipitins. 5. Animals which are treated with dialysed typhoid cultures develop the specific precipitins in their serum. 6 There is a close connexion between the agglutinins and the precipitins.

I am greatly indebted to Dr Allan Macfadyen for the help afforded me in the course of the experiments, as well as for the performance of the necessary inoculations.

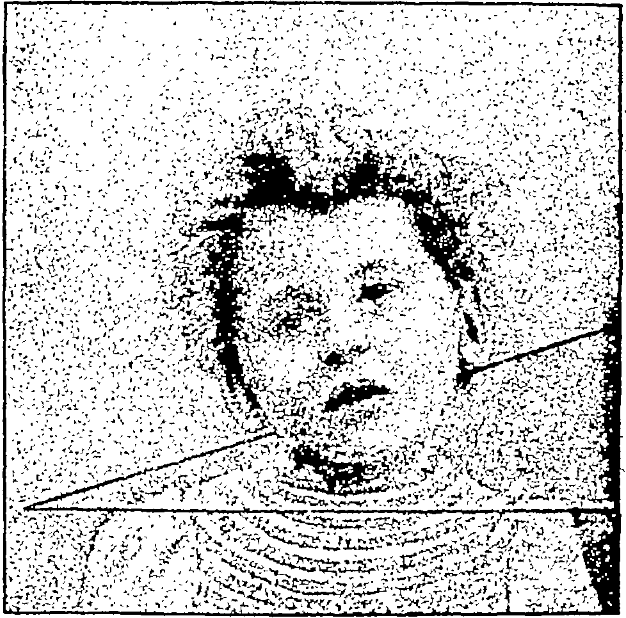
SOME PRACTICAL POINTS IN THE TREATMENT OF CONGENITAL TORTICOLLIS

BY E NOBLE SMITH, F R.C.S. EDIN.,
SENIOR SURGEON TO THE CITY ORTHOPÆDIC HOSPITAL, HATTON GARDEN E.C

THE main facts known about congenital torticollis have been described by many writers and therefore I propose to limit my remarks to a few practical points in the conduct of these cases. These points may be summarised as follows. 1. Division of the contracted sterno-cleido-mastoid muscle is usually required to cure the deformity The anterior fibres of the trapezius and also deep bands of cervical fascia are also sometimes involved. 2. A retention apparatus is not usually necessary in the treatment of uncomplicated congenital torticollis, either before operation or as a means of retaining the head in a straight position after the division of a contracted muscle. 3. In operating we have to decide between an open wound and a subcutaneous section The open wound (assuming that strict antiseptic precautions are taken) is desirable in the majority of cases and certainly it ought to be made when the clavicular attachment of the muscle has to be divided. When the sternal origin alone requires division and the contraction is sufficiently severe to cause the tendon to be raised away from the deeper tissues—then the subcutaneous operation may be performed as a safe procedure. It is impossible to divide the clavicular attachments of the muscle subcutaneously without risk of wounding some important structure, notably a vein. 4. A vertical incision between the two attachments is useful in operating, first because it is less likely to leave a noticeable scar than a transverse cut and, secondly, because we can through this one opening divide both the clavicular and sternal portions of the muscle. When other bands of contraction occur they must be dealt with according to their peculiarities. 5. The incision should be about one and three-quarter inches in length from the level of the clavicle upwards and should expose the edge of the clavicular portion of the sterno-mastoid. A director should then be worked closely under the muscle just above the clavicle until it projects at the outer border of the muscle. The vertical wound will allow the skin to be drawn to the outer side sufficiently to permit of the escape of the end of the director. Then the muscle can be carefully cut through from without downwards, the surgeon observing as he proceeds that no important vein, nerve, or artery is involved. The same method can then be applied to the sternal attachment. Oozing of blood having ceased the wound must be stitched up and treated in the ordinary manner, a large pad of gamgee tissue or other soft dressing being applied to effect gentle pressure. The dressing should be fixed with adhesive strapping and a bandage. The patient's head should then be placed in a perfectly straight position or even a little bent towards the side opposite to the affected muscle and fixed in position by sandbags placed on each side of the head, the patient lying supine. No other method of retention is necessary unless the child should be very unmanageable. The divided muscle usually reunites rapidly and about from a week to 10 days in bed in the one position suffices usually to allow a fairly firm union to take place. After this it is generally permissible for the patient to sit up in bed and in the course of a few days to get up and move about cautiously. At the end of three weeks the patient should have recovered from the operation. 6. The subsequent treatment depends upon the condition of the patient previously to operation. In the case of a young child, say five or six years of age or even older, it is probable that the structural changes in the spine from the previous malposition of the head will not be severe and that when the contraction is relieved the patient will have little or no difficulty in keeping the head straight. If there should be an inclination on the part of the patient to drop the head towards its former malposition a course of massage and special exercises will suffice to correct this tendency. In proportion to the length of time which has elapsed before operation has been performed, or, in other words, in proportion to the age of the individual and also in proportion to the degree of the contraction, so will be the tendency to deformity of the neck. It is in the older patients, and especially in adults, that the spine and other structures will have changed their shape, so that a very decided inclination for the head to assume the old position will exist. But even in these cases massage and exercises will generally suffice in a few weeks or months to overcome the evil. We may, of course, meet with severe lateral curvature as a result of the deformity and then such a complication will require to be separately dealt with, but these cases are comparatively rare and hardly come under consideration in a paper dealing with uncomplicated congenital torticollis. Of course, patients ought never to be allowed to continue to adult age unrelieved but such cases certainly exist. It is probable that a fear of bad results from operation—a fear which with antiseptic surgery and care in operation ought not to be entertained—explains the fact that this affection is sometimes allowed to continue beyond childhood. In some cases other muscles besides the sterno-mastoid are contracted, but these do not come into the category of uncomplicated congenital torticollis. Nor, I may as well add, am I considering those instances of contraction due to tonic spasm caused by caries of the cervical vertebræ and other causes.

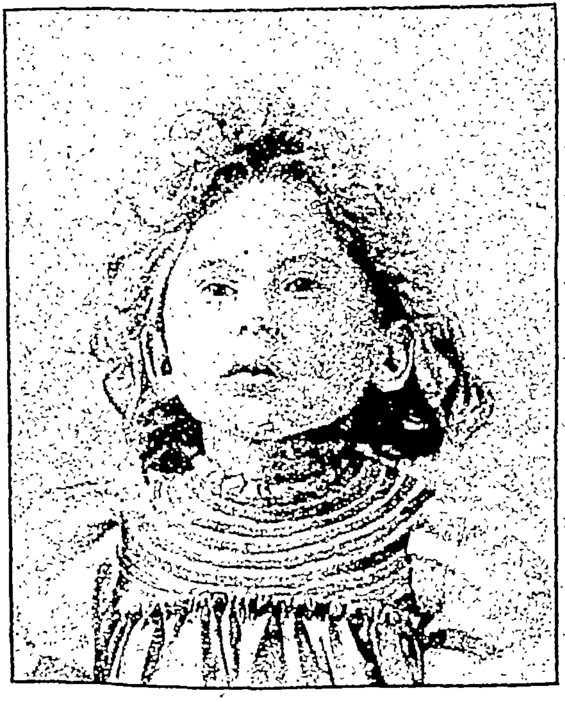
CASE 1.—The patient, a girl, aged three years and three months, was sent to me by Dr. F. A. Purcell on June 11th, 1895. The right sterno-mastoid was contracted, drawing the head down on that side, as shown in Fig. 1. It is possible that in this case the contraction was due to injury to the muscle from the force which was necessarily employed in delivering the head at birth, the case being a breech-presentation although, of course, this may not be the explanation of the contraction. In the treatment of the torticollis it was necessary to divide both the sternal and clavicular attachments of the contracted muscle. The head was immediately placed in a straight position and perfect union took place rapidly, so that in three weeks the child was well and about again. Four months after operation the head remained perfectly straight and the father took the second photograph.

FIG. 1.



The patient in Case 1. The lines show the amount of deformity, one line being at the level of the shoulders and the other at the level of the lobes of the ears.

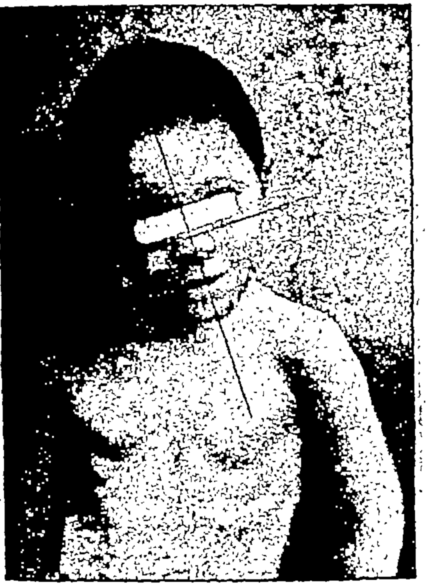
FIG. 2.



The same patient four months after operation.

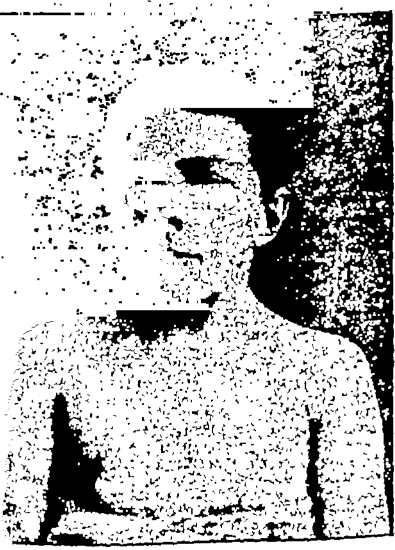
CASE 2.—The patient, a boy, aged five and a half years, was sent to me by Mr. J. Keay of Stockport in April, 1896. This patient is shown in Fig. 3 and it will be observed that

FIG. 3.



The patient in Case 2 before operation in April, 1896. The whole trunk was curved in accordance with the bend in the neck. The lines show the amount of distortion of the head.

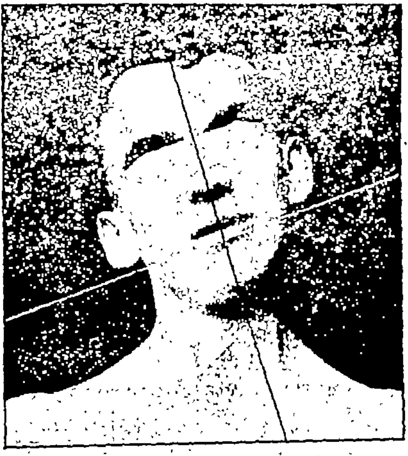
FIG. 4.



The same patient in April, 1901, five years after operation, showing that he was absolutely cured of the deformity and remained sound.

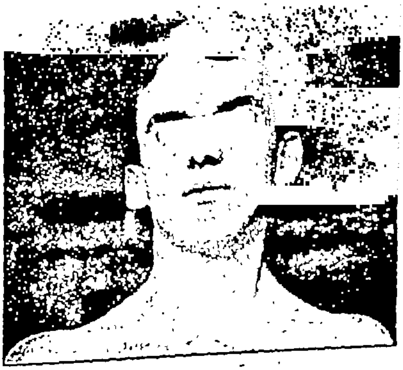
the whole body is curved in correspondence with the deflection of the head—that is to say, *from the vertex of the head to the pelvis is one continuous curve*. In this instance the spine had become involved as a result of the torticollis and I found it necessary to use an apparatus for a time *for the spine itself*. I therefore took the opportunity to extend this apparatus to the head. Had the spine not been thus affected I should not have used any apparatus and from more recent experience I believe that the case would have done very well without the head-piece. On April 10th, 1896, I divided both the attachments of the sterno-mastoid. The patient made a rapid recovery and a few weeks after operation the head was retained in a perfectly straight position. I had the opportunity of seeing this patient in April, 1901, five years after operation, and I found the cure to be absolutely perfect and I therefore took the photograph which is represented in Fig. 4.

FIG. 5.



The patient in Case 3 before operation. The lines show the deflected position of the head.

FIG. 6.

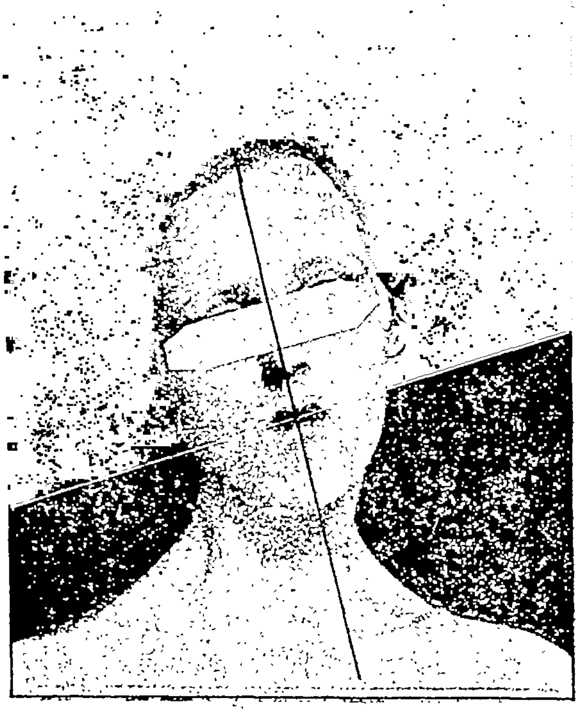


The same patient a few weeks after operation.

CASE 3.—The next case is instructive as showing the effect of torticollis being allowed to continue without treatment until adult age. In such instances it is almost certain that structural changes will have occurred in the spine and other parts requiring longer after-treatment, but yet, even under such circumstances, it is not necessary, as a rule, to use apparatus. The patient, who was 21 years of age, was sent to me by Dr. M. H. Gardiner of Richmond, on Dec. 8th, 1900. The right sterno-mastoid was contracted as shown in Fig. 5. There was also some contraction of the left sterno-mastoid, which seemed to be of a temporary nature and had probably been brought about by the continued efforts of the patient to counteract the contraction on the right side. Operation was necessary on both attachments of the right sterno-mastoid and the result was perfectly satisfactory. In a few weeks after operation the patient was able to hold *his head almost perfectly straight as shown in Fig. 6.* There was, however, a great tendency for the head to drop to the former position in consequence of the altered shape of the cervical vertebræ and other tissue changes, and a course of exercises and massage was necessary to overcome this. The patient made rapid improvement, so that at the end of three months he had complete control over the head. I considered, however, that it would take several more months before he could safely give up the exercises. After the first three weeks he had been able to carry out these exercises by himself. At the age of 14 years this patient wished to enter the navy, but he was refused in consequence of his wry-neck.

CASE 4.—A girl, aged 14 years, was sent to me on March 5th, 1901, by Miss Rigby, a member of the Ling Association, who had been *treating* her with exercises *for* curvature of the spine. As seen in Fig. 7, the contraction was chiefly on the right side, but partly also on the left.

FIG. 7.

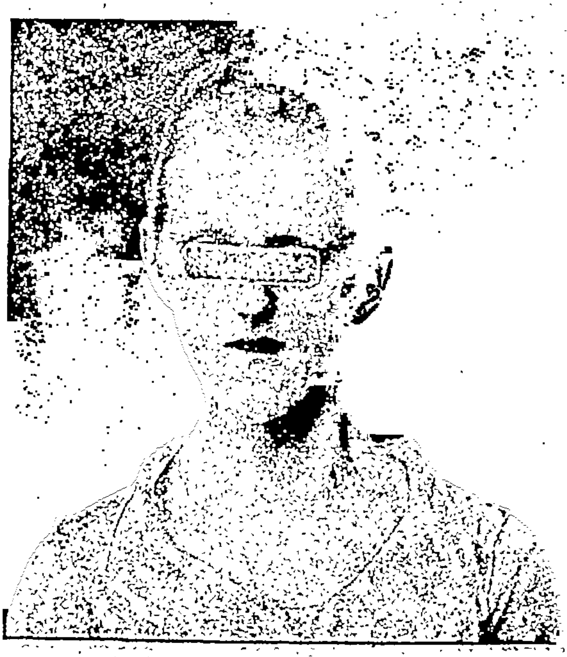


The patient in Case 4. Before operation, the lines show the deflected position of the head.

It had been thought that the position of the head was due to the curvature of the spine, but it is more probable that the spine trouble was the result of the wry-neck. By exercises Miss Rigby had been able to overcome the curvatures in the dorsal and lumbar regions, but she failed to produce any effect on the cervical curve. This failure was not surprising as the neck was kept bent by the contracted muscle. Both attachments of the sterno-mastoid had to be divided and the patient made a good recovery (Fig. 8). It was, of course, necessary in this case to carry out a course of massage and exercises to overcome the curvature in the cervical part of the spine and the consequent tendency to drop the head towards the old position.

The whole subject of torticollis is a large one and I have purposely limited the above remarks to the simplest form which presents itself. Those surgeons who wish to study torticollis in all its forms cannot do better than consult the work of Dr. P. Redard, published in Paris in 1898, which is not only complete in itself but which gives a long list of the bibliography of the subject.

FIG. 8.



The same patient three weeks after operation.

Queen Anne-street, W.

BRIEF NOTES ON THREE CASES OF AUTO-INTOXICATION: ONE FATAL.

By A. B. DUPREY, M.R.C.S. ENG., L.R.C.P. LOND.,
ASSISTANT COLONIAL SURGEON, ST. LUCIA, BRITISH WEST INDIES.

IN Grenada and the Grenadines, where corn and peas form chiefly the staple article of food of the people, constipation is a very troublesome condition among them, so also it is with the inhabitants of the other islands where the same diet prevails. Various fruits as well which the poor indulge in, such for example as the mango, the sugar apple, and the apricot (mammy apple), are all fibrous and as such are calculated to render the bowels most obstinately constipated. It is well known that whereas the well-to-do indulge in foods that are much too rich the diets of the poorer classes are not sufficiently stimulating. Be that as it may, cases of obstinate constipation frequently present themselves, and it is a very difficult matter to persuade such patients that their diet should be altered for a more stimulating one; indeed, in very many instances there is no alternative, seeing that the parties are too poor to afford a frequent change of diet. My attention has for some years been drawn *to a series of cases* presenting *symptoms not unlike* those following upon a condition of uræmic poisoning and it has always been remarkable to me that there is not the slightest sign indicative of any Bright's disease. The urine has usually been free from the slightest trace of albumin or sugar and the patients, except for a state of stupor gradually deepening into coma, are otherwise physically healthy. Malaria cannot account for this condition, for usually in malarial coma there is always to be found a history of intermittent fever, and, moreover, the treatment adopted in the cases under discussion is sufficient to do away with any idea of malarial infection. Alcoholism is also excluded by virtue of the history and the state of the patient when he comes under observation. The only other state which might be allied to this condition is that of hysterical coma, which, in a useful means of hæmostasis and this may be made more efficient by employing at the same time a solution of suprarenal extract to the bleeding surfaces.

The best treatment of shock is preventive and to that end it is desirable to lose as little blood as possible, though I do not agree with those who assert that shock in operation is always dependent on loss of blood. The patient is enveloped in a roughly made suit of Gamgee tissue and where he is very feeble or the operation is likely to be prolonged it is performed on a heated table. A large enema of normal saline solution, with or without stimulant, given from 15 to 20 minutes before, and the administration of 10 minims of solution of strychnia subcutaneously just before commencing anæsthesia, are useful. Expedition in operating is an important factor in lessening shock, especially in abdominal surgery, for it stands to reason that prolonged manipulation and exposure of the viscera in patients so ill as are those composing the class of cases which we are now considering must generally be, will be badly borne, for it is not only the work of the surgeon, but the deep anæsthesia, that adds to the shock, since for choledochotomy to be well and expeditiously performed the muscles must be well relaxed. Choledochotomy should occupy from half an hour to an hour and in case of unusual complications a little longer, but it seems to me that the surgeon who spends two, three, or four hours over one operation is lacking either in skill or in judgment. After the operation a pint of saline fluid with one ounce of brandy is given by enema and five minims of solution of strychnia are given subcutaneously every two hours for several hours if called for. Subcutaneous injections of saline fluid or intravenous infusion are only rarely required.

As I have performed the operation of choledochotomy for the removal of gall stones from the common duct on 60 occasions it would be too tedious to read even a short abstract of them all. I shall therefore refer those who wish for more detail to the second edition of my book on "Diseases of the Gall bladder and Bile Ducts," where an account is given of all my cases, 28 in number, operated on up to Dec. 31st, 1899, and to the list of cases, 32 in number, operated upon since Jan. 1st, 1900. It is interesting to note that the mortality of the whole series of 60 choledochotomies is 16·6 per cent., or excluding the duodeno-choledochotomies 14·2 per cent., but while those operated on before 1900 give a rate of 23·8 per cent. those since Jan. 1st, 1900, show only 7·1 per cent. of deaths, and of the two fatal cases one was from heart disease and the other from pulmonary congestion and shock, both deaths I believe being essentially due to ether anæsthesia, the ether having been given by means of the old apparatus with an india-rubber bag, a method which I have discarded on account of its asphyxial tendency and its want of cleanliness. I think, therefore, that it is quite reasonable to assume that with due precautions the mortality of the operation of choledochotomy should be reduced to 5 per cent. or under.

A SUMMARY OF A SERIES OF 60 CHOLEDOCHOTOMIES.

Cases 1 to 21, inclusive, which were operated upon before 1900, have been previously reported, in 16 of these recovery ensued.

CASE 22.—The patient, aged 50 years, was seen by me with Dr. J. T. Windle of Ovenden. There had been gall-stone colic for two years and three months. There was loss of flesh and of strength. Jaundice and infective cholangitis were present. A stone was floating in the common duct and there was a fistula between the gall bladder and the colon. The operation was performed on Jan. 28th, 1900. The stone was removed from the common duct, the fistula between the gall bladder and the colon was closed, and a good recovery followed. The patient was quite well in September, 1901.

CASE 23.—The patient was a married woman, aged 44 years, who was seen by me at the General Infirmary, Leeds. There was a history of gall stones of 14 years' duration and of great failure in health. There was jaundice which was intensified after each seizure. The operations of choledochotomy and cholecystotomy, which were carried out on March 29th, 1900, resulted in a good recovery. The patient was well in 1901.

CASE 24.—The patient was a man, aged 52 years, whom I saw with Mr. W. H. Ellis of Shipley. There was a history of "spasms" lasting for some years and in later years of jaundice and infective cholangitis. There was a stone floating in the common duct. Jaundice and infective cholangitis were present. Choledochotomy and cholecystotomy were performed on June 7th, 1900, and a good recovery followed. The patient was well in July, 1901.

CASE 25.—A woman, aged 54 years, who was seen at the General Infirmary, had had colic two years previously followed by jaundice. There had been several severe attacks since with ague-like seizures and loss of weight. There were five stones in the common duct. Choledochotomy and cholecystotomy were performed on August 22nd, 1900. A good recovery resulted and the patient was well in December, 1901.

CASE 26.—I saw the patient, a man, aged 56 years, with Dr. A. G. Barrs of Leeds. He had been troubled with diarrhœa and indigestion for 25 years. The first attack of gall-stone colic and jaundice had occurred six months previously. One stone was ulcerating through the gall bladder and one was in the common duct. There was muco-pus in the ducts. Suppurative cholangitis was present. Choledochotomy and cholecystotomy were carried out on August 22nd, 1900. Posterior drainage was employed, but recovery was tardy. The patient has been well since except for occasional attacks of pain.

CASE 27.—This patient, a woman, aged 43 years, I saw with Mr. G. A. Davies of Newport, Mon. She had suffered from colic for six years and from jaundice for two months. Two recent colicky attacks had been followed by fever and rigors. There were jaundice and infective cholangitis and a stone in the common duct. Choledochotomy was performed on Oct. 26th, 1900. A rough stone was removed. Anterior drainage was adopted. After a severe attack on July 19th, 1901, another stone was passed. The patient was very well in November, 1901.

CASE 28.—The patient, a woman, aged 45 years, who was seen at the General Infirmary, had had colic for eight years. Jaundice was present and was increased after each attack. Choledochotomy and cholecystotomy were performed. Several gall stones were removed from the gall bladder and the common duct and a good recovery followed.

CASE 29.—A man, aged 52 years, who was seen at the General Infirmary, had had symptoms for 20 years—"pains, &c." There were infective cholangitis with loss of flesh and strength, a fistula between the gall bladder and the duodenum, intense adhesions, and jaundice. Choledochotomy with closure of the fistula and cholecystotomy were carried out on Feb. 15th, 1901. The patient took ether badly, became livid and had much mucus in the bronchi. He died from shock and congestion of the lungs.

CASE 30.—The patient was a woman, aged 50 years, whom I saw with Dr. H. Mitchell of Cockermouth. She had suffered from attacks of colic over a long period of time. Jaundice was moderate. There was a fistula between the gall bladder and the duodenum. There were two stones in the gall bladder and one stone in the common duct. Choledochotomy and cholecystotomy were proceeded with on Feb. 6th, 1901. The fistula was repaired. Complete and perfect recovery ensued and the patient was well in September, 1901.

CASE 31.—A woman, aged 57 years, was seen by me with Dr. F. R. Mallett of Bolton. There had been many attacks of colic, and jaundice had prevailed for three weeks. There were rapid loss of flesh and jaundice. There were a stone in the common duct and one in the gall bladder. The gall bladder was calcareous, forming a hard tumour. Choledochotomy and cholecystectomy were performed on June 8th, 1901, and a good recovery followed, the patient being very well in November, 1901.

CASE 32.—A woman, aged 40 years, was seen by me with Dr. F. W. A. Godfrey of Scarborough. For three years she had suffered from colic and jaundice. Jaundice and infective cholangitis were present and there were eight stones in the gall bladder and one in the common duct. Choledochotomy and cholecystotomy carried out on June 17th resulted in a good recovery. The patient was very well in November, 1901.

CASE 33.—I saw this patient, a woman, aged 48 years, with Dr. T. Wakefield of London. Colic had persisted for one year and there was jaundice. There was a fistula the result of a previous operation performed elsewhere in October, 1900, when two stones were found in the cystic duct. There was also a biliary fistula. Slight jaundice and rigors occurred if the fistula was not kept patent. On July 1st, 1901, choledochotomy was performed with excision of the fistula. Two stones were found in the common duct. A good recovery followed and the patient was very well in November, 1901.

my opinion, may also originate in a loaded bowel by the absorption of injurious toxins, but whereas hysteria commonly affects women alone this process of auto-intoxication affects both men and women equally. In fact, there is nothing that I see which would cause this state of stupor in patients otherwise healthy except the absorption of injurious substances consequent upon a loaded bowel, and in defence of my contention I would point out that the headache which is a usual result of constipation is very suggestive of poisoning. The treatment, moreover, is so simple and successful as to admit of no doubt of the origin of the trouble. This consists simply of a large enema of soap-and-water with two tablespoonfuls of castor oil added. The two following cases indicate the clinical symptoms of this condition.

CASE 1.—A woman was admitted to hospital in an apparently comatose state. She was well nourished and between 35 and 40 years of age. She was quite unconscious. Her face was perspiring, the pupils reacted to light and to accommodation, and the breathing was quick and shallow. The lungs and heart were normal. The pulse was full and regular, counting 96 in the minute, and the temperature was normal. The urine, which was drawn by catheter, was free from albumin. The history was that she was quite well but was seen to drop as if shot. A large enema of soap-and-water with an ounce of castor oil was administered and half an hour later she passed a very large motion, when she almost immediately regained consciousness. She was discharged well.

CASE 2.—I was called to see a young man who was taken suddenly ill and who was said to be dying. I found him unconscious but he could be roused on shaking him, when he would open his eyes, mumble a few unintelligible words, and subside again into an unconscious state. He had not been drinking. His heart and lungs were free from disease and he was not a fever subject, but there was a distinct history of constipation. There was no albumin or sugar in his urine which was subsequently examined and he was not subject to fits. I gave him five grains of calomel by the mouth and ordered the usual enema of soap-and-water and oil, which according to the attendants worked him well. On the following day he was up and about.

Such is the usual history of these cases, but quite recently a case of sudden death in a child, six years of age, was reported to me and I made a post-mortem examination the result of which suggested the writing of this note. On careful inquiry no history of any disease could be obtained from the parents which would be likely to bring about the sudden death of the child, only the mother stated that her bowels were "hard to go off." She was playing about the yard when she dropped down and almost immediately expired. The necropsy was performed in the mortuary of the St. Lucia District Hospital 17 hours after death. The body was found to be that of a well-shaped, well-nourished female child. Rigor mortis had passed off in the upper part of the body but was still present in the lower extremities. The larynx and trachea were not obstructed and appeared to be quite normal. The lungs and pleuræ were normal. There was a little less than a tablespoonful of serous fluid in the pericardial sac; there was no evidence of pericarditis. The heart had stopped in systole. The left ventricle contained a little ante-mortem clot which extended to about half an inch up the aorta. The mitral and aortic valves were perfectly smooth and normal. The right ventricle was quite empty. The tricuspid and pulmonary valves were normal. The œsophagus and stomach were normal and the latter contained about one ounce of a white grumous fluid; its mucous membrane appeared to be normal. The small intestines were normal and contained no worms. The appendix was normal; its position was upwards and backwards. The ascending colon and transverse colon were empty. The descending colon from the splenic flexure to the sigmoid was a bag of fæces, the contents being more or less a cast of semi-solid fæces, with here and there very hard fæcal masses forming lumps of about the size of a shilling. There was no sign of obstruction or contraction or any thickening whatever. The sigmoid and rectum appeared to be perfectly normal. There was only slight distension of the descending colon. The liver and the gall-bladder were normal, so were the kidneys, spleen, and pancreas, the bladder, and the uterus and its appendages. As regards the brain the calvarium was somewhat adherent to the dura mater; the pia arachnoid seemed to be normal. The lateral ventricles were normal and contained a little fluid but of no unusual quantity. The optic thalami, the caudate and lenticular nuclei, and the internal capsule seemed to be perfectly normal, so also did the pons, the cerebellum, and the medulla. The fourth ventricle was also examined and appeared to be normal. In fine, there seemed to be nothing, with the exception of the fæcal distension of the descending colon, to account for the sudden death of the child who appeared perfectly well up to the time of her death. Had she lived she would undoubtedly have suffered sooner or later from intestinal obstruction from fæcal retention. I have therefore come to the conclusion that the absorption of poisonous toxins from the bowel, which would in an adult have given rise to a suspension of consciousness until relieved by treatment, caused sudden death in the case of this child, whose vitality presumably was less able to withstand such poisons.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Proœmium.

BETHNAL GREEN INFIRMARY, N.E.

A CASE OF CHOLESTEATOMA OF THE FOURTH VENTRICLE.

(Under the care of Dr BEATRICE KNOWLES and Mr. WILLIAM HALL PEILE, assistant medical officers.)

THE patient, a well-developed woman, aged 30 years, came under observation on Sept. 19th, 1901, complaining of pains in the back of the head "like knives," a feeling of weight on the top of the head, a sensation of pins and needles in the hands and feet, and of inability to walk. She had enjoyed good health until two years previously, when she was noticed to stagger on walking; the difficulty in locomotion increased steadily, and of late she had been constantly falling down. The pains in the head and other subjective sensations were of only three weeks' duration. The patient was married; she had had six children and one miscarriage. No history of syphilis, otitis, injury to the head, or alcohol could be obtained.

On admission the patient was a well-nourished woman, of medium height, with a sallow complexion. Her mental state was dull and she was slow in answering questions but did so accurately. The speech was thick and indistinct, resembling that of a general paralytic. This the patient noticed herself and she volunteered the statement that her tongue and mouth felt swollen; the tongue, which was furred, was protruded in the middle line and was distinctly tremulous; the breath was offensive and had very markedly that peculiar odour which is often present in cases of tumor cerebri. The gait was a staggering one, with the feet wide apart and with the arms extended to preserve the balance. There was a constant tendency to fall to the left and Romberg's symptom was well marked. There was good muscular power in both lower limbs and no tenderness on pressure, rigidity, wasting of muscles, or anæsthesia could be detected. The knee-jerks were present on both sides and were exaggerated; ankle clonus could not be obtained. In the upper limbs the only thing noted amiss was a slight impairment of the muscular sense. As regards the head, there was slight but distinct tenderness to percussion and pressure all over the occipital region, but it was not more marked on the one side than on the other; there was no facial or ocular palsy or nystagmus. The pupils were equal and moderately dilated and they reacted readily to light and accommodation. It is to be regretted that the ophthalmoscope was not used at once, as the patient's sudden death prevented this being done subsequently. The bladder acted normally; the bowels were obstinately constipated, resisting calomel, salines, croton oil, and enemata, all of which were used freely.

There is not much to be said as regards the progress of the case. The patient lay quietly in bed and slept well at night; she complained of moderately severe occipital headache. There was no vomiting; the appetite was good and the temperature varied between 97·4° and 99·2° F. The pulse was normal. On Sept. 24th, five days after admission, she became restless, taking off the bedclothes and attempting to get out of bed. At intervals she would lie quietly on her left side curled up in the bed; towards evening the pulse became very rapid, respiration failed rather suddenly, and she died, remaining conscious almost to the last.

Necropsy.—At the post-mortem examination on removing the skull-cap a very congested state of the cortical veins was noted. When the brain was being removed a puncture was accidentally made in the floor of the third ventricle, out of which more than half-a-pint of cerebro-spinal fluid spurted with considerable force. On the removal of the brain a portion of the tumour was seen lying in the space between the cerebellum and pons. The tumour, which was irregularly spheroidal, had a diameter of about two inches and was roughly of the size of a Tangerine orange. The surface was very irregular and on it were numerous pearly outgrowths varying in size from that of a pin's head to that of a pea. The whole tumour had a remarkable pearly lustre which was especially marked in the smaller outgrowths. Before dissection it appeared to be growing in the space between the medulla and the cerebellum; the medulla was pushed forwards and to the right and considerably flattened; the tumour also pressed upon both lobes of the cerebellum, especially the left, and upon the vermis which was flattened out. On cutting through the inferior vermis of the cerebellum the full size of the tumour became evident and it was seen to be lying in a greatly distended fourth ventricle. On moving the tumour the floor of the fourth ventricle could be seen and at its extremity the orifice of the Sylvian iter to which the tumour was closely applied. In order to preserve the specimen no further dissection was done. The other organs of the body appeared to be quite healthy.

Remarks by Dr. KNOWLES and Mr. PEILE.—Cholesteatoma, or pearly tumour, occurring within the cranium is an exceedingly rare condition, as is proved by the fact that there was no example of it in the museum of the Royal College of Surgeons of England. In most of the text-books on medicine it is merely mentioned as a curiosity in company with psammoma. Cholesteatomata are found in three situations—(1) in pre-existing hollow spaces lined with epithelium, such as the mastoid cells of the temporal bone; (2) growing from the leptomeninges, the pia mater, or the trabeculæ of the arachnoid; and (3), as in this case, in the central canal of the cerebro-spinal system, where, according to Thoma, they arise as autonomous new formations of endothelial cells. "These tumours are waxy or mother-of-pearl-like masses consisting of shed epidermic squames and cholesterin crystals The epidermic squames are arranged in irregularly concentric laminæ and accordingly the whole mass has a rounded shape. They are sometimes primary multiple growths and are then found as a number of pearl-like tumours in the arachnoid; in other cases the originally separated pearls become united and form irregular masses" (Thoma).

A diagnosis of slowly growing intracranial tumour was made *intra vitam* and it was thought that the tumour was involving the cerebellum and probably the left lobe. The true nature of the tumour was, of course, not discovered till the necropsy, when its remarkable appearance removed all doubt. Gumma and tubercle were both suggested; malignant disease was excluded by the long duration of symptoms. It is remarkable that so large a tumour situated in such a position should have caused so little motor and sensory disturbance and that the bulbar symptoms should have been confined to a mere thickness of utterance. The specimen is now in the museum of the Royal College of Surgeons of England. For permission to publish the case we are indebted to Dr. W. J. Potts, medical superintendent.

SEAMEN'S HOSPITAL, FUNCHAL, MADEIRA.

A CASE OF DOUBLE COMPOUND FRACTURE OF THE TIBIA WITH SIMPLE FRACTURE OF THE FIBULA UNTREATED FOR ONE MONTH; OPERATION; RECOVERY WITH SOUND LIMB.

(Under the care of Mr. J. GEDDES SCOTT.)

ON Feb. 30th, 1899, a sailor, aged 19 years, was admitted into the Seamen's Hospital, Funchal, Madeira, with the following history. Four weeks previously whilst engaged in his duties on board a sailing ship he sustained a severe blow on his right leg from a block of wood. He fell down and on attempting to rise found that he was unable to do so. His companions "bound a rag" round the injured limb and removed him to his berth in the forecastle, where he lay without any further treatment until his vessel put into Funchal to obtain medical assistance. On admission to the hospital his condition was as follows. He had a compound fracture at the junction of the middle and lower thirds of the right tibia and a compound fracture just below the point of junction of the upper with the middle thirds of the same bone. The fibula on the same side had sustained a simple fracture about the middle of the bone. Both wounds on the tibia were suppurating, the lower one having a deep sinus which lead down to dead bone. They were surrounded by unhealthy granulations and the whole leg was swollen and œdematous besides being exceedingly painful. The patient's temperature was 100° F. Both fractures showed good examples of vicious union, the upper having united with the convexity slightly outwards and the lower with the convexity forwards and inwards. The fracture of the fibula was ununited. In the absence of the surgeon the physician to the hospital, Dr. R. Krohn, asked Mr. Scott to operate.

The patient having been anæsthetised Mr. Scott cut down on to the projecting pieces of bone in both wounds, raised the periosteum, and with a bone forceps and chisel removed the projecting fragments together with some superfluous callus and dead bone. He removed with a sharp spoon the unhealthy granulations in the neighbourhood, scraped the sinus after laying it open, and stitched the edges of the wounds together with silk. Having set the fracture of the fibula as well as possible under the somewhat difficult circumstances, the parts were dressed with lint wrung out of a solution of perchloride of mercury (1 in 2000). The dressings were left untouched for a week, during which the patient's temperature fell to normal and the pain in his leg subsided. On removing the dressings the upper wound was found to have healed by first intention, whilst the lower one showed very slight signs of suppuration at its lower extremity. The swelling of the leg had entirely disappeared. After a fortnight the patient was allowed to get up. The fractured fibula had healed with apparently firm union in a good position. In a month's time from his admission he was able to get about with the aid of a stick and the leg showed about half an inch of shortening. He was discharged soon afterwards with a very sound useful limb which he was able to use almost as well as his healthy one.

Remarks by Mr SCOTT —The points of interest in the case in my opinion are the following: (1) the remarkable fact of the patient having survived a double compound fracture with two undressed septic suppurating wounds for a month with such few (comparatively speaking) ill effects; and (2) the remarkable manner in which the injuries healed under appropriate treatment and the small amount of shortening that remained.

Medical Societies.

GLASGOW SOUTHERN MEDICAL SOCIETY.—The annual excursion of this society took place on June 12th to the town of Kinross in the East of Scotland. Through the kindness of Dr. Ebenezer Duncan a visit was paid to the new sanatorium in the Ochil Hills. Leaving Queen-street Station at 1.55 P.M. and detraining at Milnathort the party to the number of 27 were conveyed in brakes to the sanatorium. This building, situated in grounds extending to 460 acres abundantly wooded with pine trees, stands on a spur of the Ochil Hills at an altitude of 800 feet. There are 60 bedrooms arranged on three floors opening behind on a corridor 240 feet in length, while to the rear are found the executive rooms, bath-rooms, &c. In the electrical room a demonstration was given of some of the instruments used in the diagnosis and treatment of various forms of tuberculous disease—including the apparatus for supplying electrical currents of high frequency and high potential, the ultra-violet light, and the Roentgen rays. At some distance on the west of the sanatorium the sewage tank is situated, screened off by a belt of trees. The method adopted in the treatment of the sewage is by bacterial purification and the necessary provision in the form of a septic tank and four filter beds with automatic alternating gear was duly examined. After inspection of the sanatorium the party drove to Kinross, where dinner was served in the Green Hotel.

Reviews and Notices of Books.

Clinical Hematology: a Practical Guide to the Examination of the Blood with reference to Diagnosis. By JOHN C DA COSTA, Jun, M D, Assistant Demonstrator of Clinical Medicine, Jefferson Medical College. Containing eight full-page coloured Plates, three Charts, and 48 other Illustrations London: Rebman, Limited. 1902. Pp. 474 Price 22*s.* 6*d.*

THE systematic and complete investigations which have been made during recent years into the changes which occur in the blood in disease have developed an entirely new factor in diagnosis and prognosis. Even yet the value which may be placed on the examination of the blood has not been fully determined, but ample evidence has been adduced to prove that by skilled observance of the variation in form and number of the corpuscles of the blood great assistance is afforded to the physician and the surgeon. The value of such an examination is increased when the percentage of hæmoglobin is ascertained, and occasionally the estimation of the specific gravity and alkalinity of the blood may also be of use.

In the volume now before us Dr John C Da Costa, jun, has given an excellent account of "clinical hematology," which forms "a practical guide to the examination of the blood with reference to diagnosis." The author's aim has been to recount the salient facts of hæmatology as they are understood at the present time, to correlate certain of these facts with familiar pictures of disease, and to apply them to medical and surgical diagnosis. When new measures of clinical diagnosis are introduced there is often a great tendency to exaggerate their power and scope. Dr Da Costa, however, has simply endeavoured to interpret the "blood report" according to its true value as a clinical sign, neither exploiting it as a panacea for every diagnostic ill nor belittling it because of its failure consistently to give the sought-for clue in every instance. The book gains in value by the adoption of this form of procedure; it gives a confidence to the author's conclusions which a more exaggerated tone would fail to do Throughout the work a minimum amount of theoretical discussion has been introduced, so that the practical side of the subject is paramount.

Intimate familiarity with technique is an essential qualification for the comprehensive study of the work. No pains, therefore, have been spared in the first section of the book—Examination of the Blood by Clinical Methods—to render the directions as minute as possible. Certain apparatus is necessary. The various forms of instruments which have been introduced are described, but the author does not hesitate to name those which have given the best results in his hands. The description of the processes employed to count the erythrocytes and the leucocytes is very lucid "Durham's hæmocytometer" is highly spoken of In this device the principles of the older instruments are embodied, together with the substitution of a self measuring pipette designed to overcome the sources of error which may occur in making blood dilutions with a suction pipette. Dr. Da Costa prefers the use of diluting fluids which contain just a sufficient quantity of a basic aniline dye to stain the leucocytes, so that they may be readily differentiated from the erythrocytes.

Section II. is entitled "The Blood as a Whole" and is concerned with the general composition of the blood, its colour, odour, viscosity, reaction, and specific gravity An account is also given of various "blood states," such as plethora, hydræmia, lipæmia, melanæmia, cholæmia, uricacidæmia, and anæmia. A large amount of information not usually found in text-books will be found in the pages devoted to these subjects.

Section III. deals with separate elements of the blood—the hæmoglobin, the erythrocytes, and the blood plaques. Their physiological and pathological variations are duly described. With the advance in knowledge of the changes which the erythrocytes undergo in disease many new terms have been found to be necessary; such words as "normoblasts," "megaloblasts," and "microblasts" are fully explained and the occurrence of these cells in morbid conditions is discussed.

Equally important is the section on "The Leucocytes." The different varieties are explained and their general characteristics are illustrated. Some excellent plates aid in this description. The condition of leucocytosis has attracted much attention within recent years Its physiological and pathological significations are becoming better understood and many valuable deductions may be drawn from its nature and extent.

The section on "Diseases of the Blood" contains accounts of chlorosis, pernicious anæmia, splenic anæmia, leucæmia, and Hodgkin's disease, in addition to a consideration of "secondary anæmia." The diagnosis of these conditions depends to a great extent upon the microscopic examination of the blood. Dr Da Costa has given a full and instructive description of the nature of the blood changes found in each disease and the practitioner will find in these pages much that will be of value to him in actual practice The section on the "Anæmias of Infancy and Childhood" will also be found interesting

The last section of the book is the largest and is headed "General Hæmatology" In it are described the changes which occur in the blood in general and systemic diseases. We may draw especial attention to the remarks on appendicitis, enteric fever, malignant disease, and pneumonia. In all of these much valuable information may be derived from an examination of the blood, especially with regard to prognosis. An excellent account is given of the malarial parasite and the plates illustrating the various forms are some of the best that we have seen.

We can cordially recommend this book to those who desire information on a branch of medical science which is at present not widely known but which promises to be much more prominent in the near future than it has been in the past.

The Æstivo-Autumnal (Remittent) Malarial Fevers. By CHARLES F CRAIG, M.D Yale, Acting Assistant Surgeon, U S Army, Pathologist and Bacteriologist to the U S Army General Hospital, Presidio of San Francisco, Cal; late Director of the Bacteriological Laboratories of the Sternberg U S A General Hospital, Chickamauga Park, Ga., the Josiah Simpson U S A General Hospital, *Fortress Monroe*, Va., and the Camp Columbia U S A Hospital, Havana, Cuba, Member of the American Medical Association, the American Microscopical Society, &c. Illustrated by Two Coloured Plates and 21 Clinical Charts. *London* Baillière, Tindall, and Cox. 1901. *Pp* 221 Price 10*s* 6*d* net.

THERE are two questions which at once occur to the reader and reviewer of every book claiming to be of a scientific and practical, and not of a merely speculative, character—namely, whether its author has had a sufficient field for observation and such opportunities for studying a subject as to make what he has to say about it worth reading, and whether he has set forth the results at which he has arrived clearly, intelligibly, and with a definite end in view We may say at once that in these respects the reader of this book will not be disappointed. A glance at the title-page suffices to show that the official positions which the author has held and the special work on which he has been engaged afforded him a good field and excellent opportunities for observation and that he is consequently enabled from both a scientific and a practical point of view, to speak with some authority on the subject of which he treats. We quite agree, by the way, with the spirit of what Sir Frederick Treves said the other day in his address at Charing Cross Hospital about the romance of medicine. No better instance could be cited to illustrate this point of view than that of the modern history of malaria. Not only has the study of the parasitic cause of malaria in its cyclical phases in relation to man and mosquito afforded material of keen scientific interest to the microscopist, naturalist, and pathologist, but the knowledge that has been acquired has this great advantage, that it can be, as it has been, practically applied to the purposes of life with the prospect of being fruitful of present and prospective advantages to humanity. To take one practical point illustrative of the importance of a knowledge of malarial fevers, and especially of remittent malaria fever, we may refer to what occurred at Chickamauga Park camp. The author tells us that hundreds of cases of typhoid fever, pure and simple, were erroneously diagnosed and treated as remittent malarial fever at that camp and that it was largely owing to this mistake that the fever epidemic occurred which compelled the evacuation of the place as a camping-site for the troops in the late war with Spain. A microscope and Widal's test and the systematic application of them by those properly trained in their use, the author contends, constitute all that is necessary for the recognition of these two forms of fever—malaria and typhoid. He deals more especially with the æstivo-autumnal (remittent) malarial fevers; the subject of hæmoglobinuric fever is not considered. Chapter I. starts with the Definition and History of Æstivo-autumnal Fevers. Chapter II. describes the Parasites; Chapter III. deals with the Crescentic, Ovoid, and Flagellated Forms of Æstivo-autumnal Parasites, and this is well and interestingly done; and the same may be said of chapters numbered IV., V., and VI. In Chapter IV. on the Life-cycle of the Parasites within the Mosquito a brief summary is given (pp. 38, 39) of our knowledge of the life-cycle of the æstivo-malarial parasite in man and in the mosquitoes respectively and interdependently in their mutual relations to one another. The chapters dealing with Etiology, Pathology, Clinical History and Features, and Latent Masked Forms and Combined Infections, and those concluding the work on the Complications and Sequelæ, the Diagnosis and Prognosis, and the Prophylaxis and Treatment of Æstivo-autumnal Fevers, also strike us as being full and good. The author of this volume is well posted up in the literature of his subject and has evidently had ample opportunies for making microscopical examinations of the blood and a number of minute observations. It is a book that can be honestly recommended to medical officers of the public services and to all who may be called upon to treat malarial disease or are likely to practise their profession abroad.

Peru History of Coca. By W. GOLDEN MORTIMER, M.D., Fellow of the New York Academy of Medicine. With 178 Illustrations. New York: J. H. Vail and Co. 1901. Pp. 576. Price $5.

WE imagine that all that can be said about coca, "the divine plant of the Incas," has been said in this large volume and a good deal is written also about many other matters ranging from the anatomy of the vocal cords and voice production to gold-washing. Scientific literature would indeed be swelled enormously if treatises of the dimensions of this volume were written upon all the specific principles known of many other divine plants, for surely coca is not the only plant that has been called "divine." The book is dedicated to "Angelo Mariani, Paris, France, a recognised exponent of the divine plant and the first to render coca available to the world." Coca has undoubtedly yielded certain principles of value in medicine but hardly comparable in this regard, surely, with the value, say, of cinchona or nux vomica. Nevertheless, the history of coca as "the divine plant of the Incas" is interesting if it only gives one more illustration of the craving of man for a stimulant of some sort. Moreover, the Incas are an interesting race and the volume before us is more instructive in regard to anthropology than in regard to therapeutics. According to the author the use of the word "stimulant" is invariably misunderstood, most people taking the word to indicate something which arouses flagging energy, as the spur to the horse, only to be followed, however, by a reaction, a more lethargic condition than before. Whatever the strict meaning of stimulus may be taken to be, coca arouses energy without any tax upon the resources and without any despondency ensuing or diminution of activity resulting. At least, such is the view of Dr. Mortimer. The gentleman who has devoted his life-work to rendering the divine herb popular is M. Mariani of Paris, to whom coca is "a recreation, a relaxation, and a source of pleasure wholly removed from sordid commercial interest." *Vin Mariani* is, however, well known, we believe, and "eminent artists and sculptors have painted and chiseled some dainty examples which serve to typify their esteem for a modern elixir vitæ." Further, "famous musical composers have sung their hosannas in unique bars of manuscript melody," and "poets and writers have versed the qualities of the coca leaf," "royalty have set upon it their meritorious seal of patronage," and, lastly, "the modern church, more liberal than its edicts of long ago, has welcomed its use," for the Pope has approved it and "his Holiness has been supported in his ascetic retirement by a preparation of Mariani's coca, of which a flask, constantly worn, is, like the widow's cruse, never empty." Such rubbish is not creditable to a medical man.

Clinical Lectures on Neurasthenia. By THOMAS D. SAVILL, M.D. Lond., Physician to the West-end Hospital for Diseases of the Nervous System. Second edition. London: Henry J. Glaisher. 1902. Pp. 171. 5*s.* net.

THIS little work consists of five clinical lectures delivered at various times at the Paddington Union Infirmary and at the Welbeck-street Hospital for Diseases of the Nervous System. For the present edition the text of the first edition has been revised and a few alterations have been made. The first lecture deals with the different explanations put forward to explain the nature and cause of "functional" disorders of the nervous system—namely, those unattended by structural changes discoverable by the present means at our disposal. The second lecture defines neurasthenia and briefly describes the general symptoms. The next lecture deals with differential diagnosis and tabulates the differences between neurasthenia, hysteria, and hypochondriasis. Emphasis is laid on the relation of gastric disorders to neurasthenia and it is pointed out that in the majority (three-fourths) of cases of neurasthenia with gastric disorder the gastric trouble precedes the advent of neurasthenia. The fourth lecture refers briefly to neurasthenia which may follow influenza, fatigue, shock, and traumatism. Much needless repetition occurs in the chapters above referred to. The concluding lecture deals with neurasthenic insanity, the description being, however, sketchy and inadequate; while the single illustrative case cited of this form of insanity appears to be open to doubt as a genuine example of this affection. A small bibliography is appended to the work.

LIBRARY TABLE.

Regional Anatomy of the Head and Neck, for Students and Practitioners of Dentistry. By W. T. ECKLEY and C. B. ECKLEY. London: Henry Kimpton. 1902. Pp. 240.

86 Illustrations in the text and 20 Plates in black and colours. Price 12*s.* 6*d.* net.—This work is intended as a guide to those departments of anatomy with which the dental surgeon is particularly concerned. The authors state that they have endeavoured to keep practical applications in view and they certainly have succeeded in producing a most useful book for the student and practitioner. In addition to the more purely anatomical matter there is much useful information bearing on the practice of dental surgery. For example, there is a good account of the reflex pains in connexion with the trifacial nerve, including some valuable suggestions for carrying out a methodical examination of patients suffering from trigeminal neuralgia. In describing operations the authors indicate clearly the structures to be divided and the structures to be avoided. The text, which is throughout clear and concise, is accompanied by some excellent illustrations which are slightly diagrammatic.

The Essentials of Histology, Descriptive and Practical, for the Use of Students. By E. A. SCHÄFER, F.R.S. Sixth edition. London: Longmans, Green, and Co. 8vo, 1902. Pp. 416. Price 9*s.* net.—We have already had on several occasions to speak in high terms of approval of this work which has become a classic. Though it is not comparable with the great handbook of Histology of Professor Kölliker in fulness of detail it is far better adapted to the wants of the student, and it has the still greater merit of completeness, for whilst Professor Kölliker's treatise, commenced long before the date of 1889 on its title-page and promised to be completed, if health permitted, in 1890, is only about half finished in this year of grace 1902, Professor Schäfer's work after reaching its sixth edition is brought to a close and contains the results of all recent observations given in a very clear and instructive manner. It is rendered more instructive by the introduction into the text of a large number of excellent illustrations. Professor Schäfer, we are sure, would be the last to recommend the student to learn histology from its pages, but with a few instruments, solutions, and staining agents the "Essentials of Physiology" will enable the learner to acquire and to comprehend all that it is requisite for him to know in this department of medical education.

A Life Tragedy and other Verses. By WILLIAM TEUCER. London: John Bale, Sons, and Danielsson, Limited. 1902. Pp. 64. Price 2*s.* 6*d.* net.—Mr. Teucer intimates that "half the profits resulting from the sale of the first edition of this volume will be given to the King Edward's Hospital Fund." This being so, we desire to call attention to a bold figure which Mr. Teucer has, in the exercise of his poetic licence, employed with great effect. It occurs on page 58, in the last stanza of a poem addressed to two friends on the anniversary of their silver wedding:—

"Skipper and mate, they have sailed the deep
For twenty years and five—
May the days to be
Run peacefully,
And find them still alive,

And happy, when the log records
The fiftieth milestone gone—
And a favouring breeze,
And summer seas,
To waft them on and on."

JOURNALS.

The Practitioner.—The June number deals extensively with the subject of malignant disease of the uterus. Dr. Arthur H. N. Lewers contributes an article coping mainly with the treatment of this common and disastrous condition. Dr. Lewers has abandoned supra-vaginal amputation in favour of vaginal hysterectomy for cases of cancer of the cervix. He gives details of 61 cases—33 of supra-vaginal amputation and 28 of hysterectomy. 14 of the patients remained free from recurrence at periods of from four to 15 years after operation. Dr. C. Hubert Roberts supplies a comprehensive review of the present position of pathological knowledge regarding uterine malignant disease. He regards adeno-carcinoma as the most frequent type of malignant disease of the body of the uterus and includes adenoma malignum as a variety of this disorder. As regards deciduoma malignum Dr. Roberts seem to incline to the view that the growth may have different origin in different cases and that in some it may spring from fœtal tissues. A review of diseases of the kidneys includes the account of a most interesting case of double hydro-nephrosis in a child six months old.

Analytical Records

FROM

THE LANCET LABORATORY.

(1) TABLOID UREA; AND (2) TABLOID HYPODERMIC MERCURY SUCCINIMIDE.

(BURROUGHS, WELLCOME, AND CO., SNOW-HILL BUILDINGS, LONDON, E.C.)

(1) UREA in the treatment of tuberculosis has been brought into prominence during recent years. A quantity of from five to 20 grains three times a day has been administered according to the indications of the case. The tabloid is a convenient form for administration, each containing five grains of the pure carbamide. (2) Mercury succinimide appears to possess advantages over the better-known sorts of mercury for the preparation of a mercurial solution for intramuscular injection. It is said to produce no local irritation. The tabloid will be found very convenient and trustworthy as regards *dosage* in those cases where mercurial treatment by injection is desired.

VARIOUS SOAPS.

(PRICE'S PATENT CANDLE COMPANY LIMITED, BELMONT WORKS, BATTERSEA, LONDON, S.W.)

We have received no less than 12 varieties of soap from the above well-known firm as specimens made from the purest materials, and in those cases in which the soap is medicated the purest active ingredients are stated to have been employed. We have carefully submitted the toilet soaps to various tests relating chiefly to the question of the presence of alkali in excess, of irritants, and of the proportion of water. As a matter of fact, in no single instance was evidence gained of alkaline excess, while, as might be expected, since these soaps are submitted to a special milling and drying process, the moisture present was in minimal amount. It follows that the soaps are economical in use and the ingredients are well proportioned. For toilet purposes and in cases in which sensitive skins are concerned these soaps are just what they should be, free from irritants and bland in action. The samples examined comprised various toilet soaps agreeably scented in a variety of ways and some contained oatmeal. Others were for shaving purposes, as, for instance, the glycerine cream soap, while the medicated soaps contained coal tar, carbolic acid, and sulphur respectively.

ANTIPHLOGISTINE.

(THE DENVER CHEMICAL MANUFACTURING COMPANY, 451-455, WASHINGTON-STREET, NEW YORK; LONDON AGENCY, 18, JEFFREYS-ROAD, CLAPHAM-ROAD, S.W.)

Antiphlogistine is an advance on the ordinary cataplasm. It consists of a perfectly uniform yellowish paste smelling agreeably of well-known antiseptics The vehicle is a very pure clay or silicate according to our analysis. The preparation may be used with advantage as an external application in inflammatory conditions. Anti-phlogistine maintains a moist condition of the tissues and exerts a soothing effect, while on account of its marked antiseptic properties it may be used in the treatment of open wounds or ulcers.

PENFOLD'S PURE AUSTRALIAN WINES.

(J. G. THOMSON AND CO., LEITH, N.B., AND 17, FENCHURCH-STREET, LONDON, E.C.)

We have submitted to examination a number of these wines which are produced in the vineyards first planted in 1844 in South Australia by the late Dr. Penfold. The vineyards occur on slopes situated to the east of the city of Adelaide. The character and nature of the wines may be fairly well judged from the following figures of analysis which we have obtained. Mataro (port): extractives, 14·01 per cent.; mineral matter, 0·34 per cent.; alcohol, by weight 17·25 per cent., by volume 21·19 per cent., equal to proof spirit, 37·13 per cent.; fixed acids calculated as tartaric acid, 0·208 per cent.; volatile acids calculated as acetic acid, 0·09 per cent.; and sugar, 11 63 per cent. A sound wine of the character of port but very sweet. Carbinet: extractives, 2·83 per cent.; mineral matter, 0·19 per cent.; alcohol—by weight 13·15 per cent., by volume 16·24 per cent., equal to proof spirit 28·46 per cent.; fixed acids calculated as tartaric acid, 0·231 per cent.; volatile acids, 0·16 per cent.; and sugar, 0·29 per cent. A generous full-bodied wine with a Burgundy character. The amount of sugar is small. Grenache: extractives, 9·42 per cent.; mineral matter, 0·29 per cent.; alcohol, by weight 15·67 per cent, by volume 19·28 per cent., equal to proof spirit 33·79 per cent.; fixed acids reckoned as tartaric acid, 0·20 per cent.; volatile acids reckoned as acetic acid, 0·05 per cent.; and sugar, 7 58 per cent. A sound wine described as claret, but too sweet and alcoholic to belong properly to that class of wine. Tokay: extractives, 11·34 per cent.; mineral matter, 0·21 per cent.; alcohol, by weight 15·67 per cent., by volume 19·28 per cent., equal to proof spirit 33·79 per cent.; fixed acids reckoned as tartaric acid, 0·18 per cent.; volatile acids reckoned as acetic acid, 0·079 per cent.; and sugar, 10 per cent. An agreeable white wine, but heavy as regards both sugar and alcohol. Frontignac: extractives, 12·83 per cent.; mineral matter, 0·30 per cent.; alcohol, by weight 16 46 per cent., by volume 20·24 per cent., equal to proof spirit 35·47 per cent.; fixed acids reckoned as tartaric acid, 0·32 per cent.; volatile acids reckoned as acetic acid, 0 09 per cent; and sugar, 11·11 per cent. A powerful red wine with good fruity flavour. It may be said generally of these wines that they are genuine and wholesome, though on account of their big body and strength they are better adapted for invalid purposes in moderate quantities than for ordinary table use. Some of them are very strong and very sweet and may be diluted with water with advantage. As the above analyses show, having regard to the volatile acidity, the wines are sound but their high alcoholic strength is sufficient to protect them against deterioration.

BANQUET CREAM.

(HERBERT FRANCIS AND CO., 8, ARTHUR-STREET WEST, LONDON-BRIDGE, E.C.)

We published an analysis of this cream in our issue of May 24th, 1902, p. 1476, when the results were shown to be satisfactory except as regards the amount of fat. It has been pointed out to us that this result was abnormally low, arising probably from the fact that the amount of fat in cream is often apparently low owing to a want of uniformity in consistence. We have therefore selected for ourselves further samples with the result that as a mean amount of fat in three analyses the figures 33·34 per cent. were obtained. This is eminently satisfactory. The complete analysis was as follows: water, 60·90 per cent.; fat, 33·34 per cent.; curd, 5·24 per cent.; and mineral matter, 0·42 per cent. This cream has the advantage of being sterilised, whilst the characteristic qualities of fresh cream are present. As is well known, cream may be substituted with advantage for cod-liver oil and sterilised cream appears to be more digestible than raw cream.

CEYLON TEA.

(HENRY URQUHART, 16, WATER-LANE, GREAT TOWER-STREET, LONDON, E.C.)

This specimen is described as pure high grown Ceylon tea and it is well known that tea grown on high levels yields a less astringent liquor on infusion than that obtained from tea grown in the valley. This is not due apparently to any appreciable difference in the amount but probably in the kind of tannin, for there are many varieties of this acid. We found that this tea yielded an agreeable liquor free from the roughness and astringency of the strong Indian teas. Our analysis gave the following results: moisture, 4·70 per cent.; mineral matter, 5·23 per cent.; theine, 3·40 per cent.; tannin (by the acetate of copper method), 10·69 per cent.; alkalinity of the ash reckoned as potash, 1·35 per cent. These figures are consistent with the description "a genuine pure tea." Though the amount of the tannin is not notably low yet it would appear to exist in a form that is less astringent than that occurring in Indian tea. The tea is suitable when prepared in a proper manner for dyspeptics.

THALASAL.

(ARTHUR AND CO., 69, BERNERS-STREET, LONDON, W.)

The use of this solution is described as "not only far more economical and convenient than the immersion of a patient in a bath of salt water but is also more efficacious, as it may be allowed to dry on the affected part (e.g., in cases of spinal diseases, arthritis, &c.), which cannot well be done after complete immersion without risking a chill." The solution is an opalescent, colourless liquid smelling of oil of roses. Its density was 1061 which corresponds with a strength of 8·5 per cent. of common salt. Further, a mineral residue was obtained on evaporation and careful ignition amounting to 8·42 per cent. It consisted of common salt.

ORION RUBY WINE.

(SOUTH AUSTRALIAN GOVERNMENT BONDED DEPÔT, NORFOLK HOUSE, LAURENCE POUNTNEY-HILL, CANNON STREET, LONDON, E.C.)

The analysis of this red wine was as follows: extractives, 1·31 per cent.; mineral matter, 0 25 per cent.; alcohol, by weight 13·15 per cent., by volume 16 24 per cent., equal to proof spirit 28·46 per cent; fixed acids calculated as tartaric acid, 0 27 per cent.; volatile acids calculated as acetic acid, 0 067 per cent.; and sugar, 0 25 per cent. This is a sound and agreeable wine, possessing, however, a somewhat high alcoholic strength characteristic of imported Australian wines. It is a medium-bodied wine, without an appreciable amount of sugar, and suitable for use by invalids.

NATURAL HUNGARIAN BITTER WATER (LORD ROBERTS LABEL).

(KRONTHAL WATERS, LIMITED, 70, DEAN-STREET, OXFORD-STREET, LONDON, W.)

This is a good typical natural purgative water presenting constituents in kind and amount and in ratio to each other suitable for the specific purpose of a saline aperient. Our analysis gave the following results: in grammes per litre, magnesium sulphate, 23·62; sodium sulphate, 15·68; calcium sulphate, trace; sodium chloride, 2·10; and sodium carbonate, 0·62. The total saline contents are thus 42·02 grammes per litre. The density of the water was 1036. It will be seen that the amount of sulphate of magnesium preponderates somewhat over the amount of sulphate of sodium. According to some authorities the former sulphate is mild and painless, non-nauseating, and less drastic in action than sodium sulphate, while magnesium sulphate may be taken in larger quantities than the sodium salt. This water, therefore, presents the advantages just indicated, while the presence of an important amount of common salt and of an alkaline carbonate is calculated to modify favourably the purgative action of the water This water has been used extensively on the continent in gastric and intestinal catarrh and in obesity with good results. In spite of its comparatively high mineral strength the water is not so disagreeable to the taste as might be anticipated, which is an important advantage. The particular ratio of the purgative salines would seem to account for this fact. Moreover, the full dose is comparatively small. The water is clear and bright and free from organic matter.

MEDICAL AND ANTISEPTIC TABLETS

(ARTHUR H. COX AND CO., ST. MARTIN'S-PLACE, BRIGHTON.)

We have received specimens of tablets of various drugs and containing well known formulæ from the above firm. The tablets are well made and with special care directed towards accuracy of dosage. Amongst those submitted were cascara extract, phenacetin with caffeine, chlorate of potash, with borax and cocaine, potassium permanganate, quinine bisulphate, and trinitin. Very convenient for use also are the antiseptic tablets containing carbolic acid, corrosive sublimate, and mercuric iodide. The antiseptic tablets are prepared with an innocuous colouring matter, so that the stock solution of antiseptic fluid obtained may be distinguished from other solutions by its colour

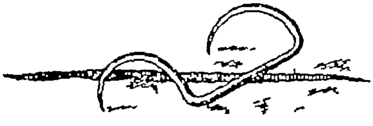
New Inventions.

A NEW METHOD OF KEEPING IN APPOSITION THE EDGES OF SURGICAL INCISIONS AND WOUNDS IN ORDER TO PROMOTE UNION

HAVING for the past three years taken a spare-time interest in the question of surgical suturing I have all along been of opinion that it was possible to devise some method which could take the place of that which has been adopted from time immemorial, notwithstanding the apparently insurmountable difficulties one met at every turn on making an attempt to solve the problem. After devising many different methods and making experiments with almost every conceivable kind of appliance I have selected that hereafter described as being by far the most effectual and practicable. The results which I have obtained from its use and the practically unanimously favourable opinions that have been given to me by surgeons of the highest rank who have investigated it are my apologies for introducing it to the profession by means of THE LANCET.

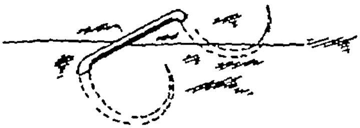
Fig 1 is a *steel* clamp consisting of a cross bar and two pointed prongs represented as lying across the edges of an incision. These prongs are curved as semicircular arcs and the plane of both is set at right angles to the cross-bar. The size of the appliance varies according to the depth of the incision dealt with but I may give three eighths of an inch for the cross bar as being about the suitable size for ordinary cuts and scalp wounds such as the general practitioner often meets. In the case of hare lip a rather smaller size is better, while a much larger size will be required for abdominal operations. These appliances are fixed in position by means of a specially designed holder which ensures a proper grip being given so that the clamp can be easily and properly placed in position. Some operators are tempted to make use of ordinary needle holders and they fail or bungle in consequence. *Once* the idea is grasped and the purport of the appliance is understood its application is perfectly simple if the right holder is used. In order to insert the clamp the holder should be gripped by the handles in the right hand, the jaws being horizontal and pointing to the left. The clamp is then placed between the jaws so that the cross-bar lies lengthwise while the points are directed to the right and downwards. Then the lower edge of the lower jaw of the holder is rested upon the skin so that the cross bar lies at right angles to the edges of the incisions, which have been brought together, and it assumes the position seen in Fig 1. Gripped and held in this position the appliance is turned round upon the imaginary axis lying between the centres of the semicircular *prongs* the result being that the points enter the flesh and the prongs are buried up to the cross-bar, as seen in Fig 2, the appliance having become inverted. A depth of tissue is thus commanded which is the measure of the radius of the semicircular prongs. The shape of the prongs and their position with regard to the cross-bar enable them to enter the flesh with the greatest ease, provided the appliance is turned round as near as possible upon the axis between the semicircular prongs. Although a very rough guess will be found quite sufficient for all ordinary purposes, it will be easily understood that the more *perfectly* this axis is judged the more perfect will be the application and results. A reverse movement (see Fig 3) will, of course, withdraw the clamp when union has taken place. The prongs having rectangular planes to the cross-bar act as powerful resistants in keeping together the edges of an incision. The curved form of the prongs gives three particular advantages: it facilitates application, it spreads resisting force over a space the measure of the diameter, and it causes the appliance to maintain its proper position.

FIG 1.



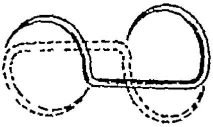
The clamp in position for insertion (enlarged)

FIG 2.



The clamp in position after insertion (enlarged) The drawing gives the effect of the prongs coming out through the skin. In practice this is not the case, the points being completely buried

FIG 3.



Showing how the clamp turns upon an imaginary axis (enlarged).

I sum up the following advantages for this new appliance: It is absolutely effectual and practicable for the main purpose required of sutures. It is more easily made perfectly and reliably sterile. It is far less irritating than an ordinary suture, not pinching the flesh together too tightly, hindering circulation. It can be applied and removed in a fraction of the time that it takes to complete the application of an ordinary suture and with much greater ease. It is suitable for practically all depths of incisions. It can be used over and over again. Instead of its being less useful in the case of opposed parts that need a good deal of drawing together, as some surgeons have at first thought, it happens to be far more advantageous in such cases by reason of the fact that the pull is not upon a single point as would be the case with an ordinary suture but upon a space the size of the diameter of the prongs. Thus in cases where stitches might pull out this appliance will hold very firmly—one of the smaller sizes will be found particularly useful in hare lip cases for instance.

The clamps and holders are made for me by the "Improvements" Supply Association, 16, Eden-street, Kingston-on-Thames.

HAYDN BROWN, L.R.C.P. Edin., &c.

Surbiton.

THE LANCET.

LONDON: SATURDAY, JUNE 28, 1902.

The Illness of His Majesty the King.

To the great grief of all his subjects it became known in London early on Tuesday morning that His Majesty the King was seriously ill.

We are able to state that an abdominal operation was successfully performed on His Majesty by Sir Frederick Treves on Tuesday morning. The anæsthetic was administered by Dr. Frederic Hewitt and was borne well, His Majesty recovering consciousness without any ill-effects whatever. The operation was attended by no complications; a large abscess was found and evacuated.

The present number of The Lancet, although it will bear the date of the 28th of June, will be in the hands of our readers some three days before that time, as we arranged for its publication before the ceremonies of the coronation. But now the royal processions through the streets of London, to which hundreds of thousands of the subjects of King Edward and Queen Alexandra, hailing from all parts of the world, have so long looked forward with eager anticipation, have been indefinitely postponed. The solemn and magnificent rite at Westminster Abbey which was to set the symbol of sovereignty over a vast empire upon the brow of one whose career as Heir Apparent had fully qualified him for the higher dignity and responsibility of kingship cannot, alas, at present be performed, for the central figure in the ritual lies upon a grievous bed of sickness. The deep anxiety of his subjects in the critical position in which their ruler is now placed is marked on every face. He has convinced his people of his zeal for their welfare and of his ability worthily to uphold the traditions of the throne. Throughout his life he has not only performed with exactness and willingness the duties that came in his way as the natural consequence of his position, but he has sought work and done it in many directions for the good of those whom he was to reign over. This is known to all, and as we acknowledge the influence of the powerful and practical sympathy which has ever been displayed by His Majesty with sickness and suffering our hearts go out to him on his bed of pain. We need hardly remind our readers of such recent incidents as his presiding at Marlborough House over the foundation of the National Association for the Prevention of Consumption in July, 1898, or of the keen interest which he has evinced in the investigation into the causes and possible prevention of the dreaded scourge of cancer. In such matters as these his has not been the perfunctory intervention of an exalted personage; his grasp of the subject has been real and his action judicious and effective. He has acted obviously upon deeply moved feelings and we may be sure that in his turn, now that he has been struck down by illness, he is receiving from his people no mere loyalty of lip-service but the truest and most affectionate sympathy.

King Edward's fellow-invalids of all sorts and conditions have particular reason to bless his name and to pray earnestly for him in his hour of trouble. In 1897 Her Majesty Queen Victoria celebrated her Diamond Jubilee, when her eldest son found himself called upon to assist the decision of her subjects as to how they might best commemorate the occasion. On the 6th of February the newspapers contained a letter signed by His Royal Highness which inaugurated the Prince of Wales's Hospital Fund for London. King Edward in that letter exhibited the warm-hearted feeling for the needs of his poor subjects, the appreciation of the demands of the occasion, and the business-like grasp of detail that have always been prominent in his actions and utterances. He showed that he knew well that the fittest object on earth for assistance of every sort—ungrudging, open-handed, and immediate—is the sick man whose purse cannot command adequate medical attention, suitable diet, or a proper environment. By his prompt recognition that the sick poor of the metropolis constituted a class with paramount claims upon him, as the figurehead of the kingdom, he proved himself to be at the same time observant, practical, and tender-hearted. It is not only, moreover, with his more conspicuous actions that the medical profession associates the zeal of King Edward in the cause of the sick and the suffering. Over and above aid given in the raising of funds on behalf of individual hospitals or by ready participation in the opening ceremonies that inaugurate new buildings, new wings, and new wards,—besides all these, there have been acts of kindness and individual sympathy that have won hearts even more completely because fewer have known of them. There have been visits to hospitals without ceremonial accompaniment, informal inspection of organisation and detail, kind words spontaneously spoken but ever remembered by those whose claim upon royal attention lay only in the fact that they were poor and in pain. Instances of unpretending kindliness such as these show that amid the conventional surroundings of royalty the King, and here we should include also the Queen of this great realm, are endowed with a human sympathy that holds nothing human alien to it. To the sweet lady whose smile has inspirited and whose voice has cheered so many of her humble subjects the heart of those subjects goes out to-day in her sore trial.

The King is no stranger to illness and suffering. The deep anxiety felt by this country when he lay upon a bed of sickness more than 30 years ago will still be remembered, as well as the gloom that overshadowed the British dominions when the grave relapse of Dec. 8th, 1871, was made known. Eagerly every symptom of recovery was noted in the constantly issued bulletins throughout the world and great was the rejoicing that celebrated the PRINCE of WALES's restoration to health The country must be prepared to go through a similar period of sickening apprehension. We do not belittle the gravity of His Majesty's condition when we urge that it is quite a common one, relieved daily in our hospitals by just such an operation as has been successfully performed upon him, nor do we magnify its gravity when we say that until convalescence is established every symptom must be watched with the deepest solicitude. In the circumstances Sir FREDERICK TREVES's address on appendicitis which is published in our columns this week will have an absorbing interest for our readers. All our surgical records serve to show that much apprehension of evil sequelæ cannot be justified. In GOD's hand is the issue.

Neither the King nor the Queen requires any further proof of the love of their subjects, but had this been needed the heartfelt outburst of grief at the tidings of His Majesty's illness would have furnished it. No one who has witnessed the preparations for the present week in London, or in the country, or throughout the colonies and dependencies of the mother country will have failed to note the spontaneity and zeal which have distinguished everything that has been done In the metropolis, to which hundreds of thousands have flocked to witness the coronation processions, the outward manifestations of loyalty have by no means been confined to the routes to be traversed or to the organised efforts of municipalities or of groups of wealthy citizens. London has been decorated throughout, in the humblest streets and houses as well as in the most important squares and thoroughfares. And similarly the sadness of the tidings of his grave illness has affected the palace and the cottage, the spacious squares and the narrow slums. Before we again have an opportunity of addressing our readers fuller details of his illness will be forthcoming, while a stage in his recovery will have been reached, at which it is reasonable to hope, our apprehensions will be greatly allayed. Writing as we do within an hour of the performance of the operation upon His Majesty it would be idle to speculate further than this.

But to one point in the first bulletin we must draw attention. It is evident that the KING fought with the utmost gallantry to fulfil his great engagement, an engagement the constitutional importance of which is enhanced by its sanctity Indeed, it is possible that had he not resisted so strenuously the idea of a postponement of the Coronation ceremonies he might have escaped the ordeal of the surgeon's knife The ceremonies of the Coronation could hardly fail to prove exhausting, even to a vigorous physique. Yet, despite his pain, the KING had braced himself to go through with them at all cost, until, fortunately in time to avert a tragedy, nature proved too strong for him. Men of our nation cannot fail to recognise and admire the courage which fought so nearly to the end and despite all risks that the people might not be disappointed. We all love a brave man, and when His Majesty King EDWARD VII. resumes his place among his people he will find them moved to the depths of their heart in gratitude for his restoration to them

Musolino the Brigand.

AFTER a trial of well nigh three months' duration at the Lucca Assizes the "ROBIN HOOD of Calabria" has been condemned to penal servitude for life, the first eight years of that term to take the form of "carcere cellulare"—that is, of solitary confinement. The proceedings were instructive and interesting from many points of view—judicial, medical, and social. Tedious at all times, Italian forensic procedure is trebly so in criminal cases when counsel for the prosecution and the defence outvie each other in a discursive loquacity, encouraged rather than checked by the presiding judge. Every circumstance affecting MUSOLINO conspired to accentuate this phenomenon. He was the popular idol of a region where law is traditionally more honoured in the breach than in the observance, and witnesses in his behalf were as formidable in number as they were prolific in evidence, exculpatory or palliative Was he not a self constituted redresser of social inequalities, "rectifying the financial *frontier*" by a free handed bestowal on the poor of the money he extorted from the rich? Was he not "agin the Government," defying the police so successfully that the military had to take the field against him? Did he not for years outmanœuvre regiment after regiment, discrediting their commandants and digging the grave of many a professional reputation? Had he not the makings in him of a guerilla leader, prompt to utilise every local advantage? That with such a career he should have been defended by criminologists of the LOMBROSO school as little better than an anthropoid ape or pithecoid man is barely credible, but such is the fact. The public prosecutor and his adjutants had seriously to rebut plea after plea as to his being a "criminal nó" or an "epileptoid" or a "tuberculotic imbecile," to quote a little from the terminology of LOMBROSO or FERRI, but, to do him justice they were spared a good deal of trouble in this direction by MUSOLINO himself who indignantly resented the pseudo-scientific "attenuanti" set up in his defence and sought to vindicate his conduct and career on the Baconian plea of the "wild justice of revenge." That there were features intellectual and moral in his nature on which psychiatry and sociology would do well to ponder is undoubted, and accordingly we are promised an elaborate study of his case by two of the first medico-psychologists of Italy in the forthcoming "GIUSEPPE MUSOLINO di Fronte alla Psichiatria ed alla Sociologia Rapporti e Considerazioni dei Professori E. MORSELLI e S. DE SANCTIS"—the former director of clinical psychiatry in the University of Genoa, the latter lecturer on medico-psychology in the University of Rome. Till this authoritative treatise is made *publici juris* it would be idle to plunge into the "hideous welter" of expert evidence adduced by counsel for the defence, but meanwhile, as preparative to its perusal, it may be well to consider the atmosphere, social and traditional, in which MUSOLINO and thousands like him are born and developed. In Calabria, more perhaps than in any Italian province, life is cheap, even the ties of parental love being elastic enough to admit of the annual sale of children to itinerant "impresarii," by whom again they are sold to organ-grinders and strolling mountebanks in the capitals of Europe. Laws prohibitive of this nefarious traffic are evaded with a success that proves the discredit into which legal authority of every kind has fallen, particularly in Southern Italy. Not to the judicial tribunals, too often venal, invariably so blocked by cases remanded or awaiting trial that years elapse before justice can be pronounced,—not to such tribunals does the victim of wrong or injury look for redress but rather to private *vendetta* aided by sympathising relatives or friends. Add to this that hardness of living as to food and shelter robs the prison of its terrors and that the abolition of capital punishment still further minimises deterrents and we are in a position to understand the great criminal statistician Baron GAROFALO when he says: "Take Europe, *minus* Spain and Portugal (the Iberian peninsula), and you will find more murders committed year by year in Italy than in all the other European countries put together." In fact, as the same eminent authority pointed out in a memorable "conferenza" held in Rome some years ago, "an Italian kills an Italian every two hours," the homicides throughout the kingdom being seldom below 4000 annually, and in the year before the said "conferenza" amounting to the ghastly total of 4380. As a contributor to these figures MUSOLINO is only some units in advance of contemporary brigands in Sicily and Sardinia, while every youth who carries the prohibited "coltello"—the "accursed knife," as ANTONIO GALLENGA called it—is a potential homicide, under the all too frequent provocation of vinous excess or that master demon of the Italian proletariat—jealousy or disappointed love. Well may Italy feel mortified at the sinister priority she maintains in "*fatti di sangue*." Well may she take it to heart that the anarchist, in precept and in practice, finds so many exemplars among her sons.

◆

On the Treatment of Early Mental Cases in General Hospitals.

A FEW weeks ago we commented in a leading article on what may be considered the burning question of the moment in the subject of insanity—viz., the treatment of early cases of mental derangement in general hospitals. Two papers bearing on this subject have recently been read, one by Dr. J. W. SPRINGTHORPE at the April meeting of the Medical Society of Victoria, the other by Dr. NATHAN RAW before the Liverpool Medical Institution in February of this year, and both were published in THE LANCET of June 14th. We commend their perusal to our readers, for the question with which they deal is of great importance to all medical men. Though Dr. RAW'S paper deals essentially with the correlation between mental and bodily diseases (and this part of his paper we do not now discuss) he declares towards the end of it his sense of the advantages to be derived from the treatment of most cases of early mental disease in reception-houses. Dr. SPRINGTHORPE also advocates the erection of reception-houses thoroughly equipped and managed by a scientific staff. All this is in the direction which we have indicated, and it is satisfactory to note that the scheme which we advocated for the metropolis appears to coincide with the views of colonial and provincial experts. A great number of early mental cases are at the present moment treated in the out-patient rooms of general hospitals, and among these we may specify St. Thomas's Hospital in London and the General Hospital at Sheffield; and it would, we think, be well that other hospitals should establish clinics of this kind to be conducted by the lecturers on psychological medicine. A certain proportion of these out-patients will, perhaps, be found to require more special treatment and as they will usually be unsuitable for the wards of the general hospital (at any rate in London) they can be sent to reception-houses for detention until it is seen how the disease develops At the same time it seems to us that there is some tendency to optimism in the present rush to treat all acute mental disease in general hospitals. Whilst agreeing with the principle of dealing with cases of this sort in general hospitals as much as possible, it must not be forgotten that the asylum must still remain a necessary fact for many persons and that the less that is said about the "stigma of certified insanity" the better it will be for those who have to go through asylum treatment. Whatever "stigma" there is will be much more accentuated if it appears that a person fails to pass the test first of the out-patient room and then of the hospital or reception-house. It is greatly to be regretted that the fact that an individual has to be placed under certificates for his own protection, or more often for that of his property, should be deemed discreditable or opprobrious. The bugbear is more in the minds of others than in that of the patient himself, and it should no more be esteemed a disgrace that a person has had to be treated in a hospital for mental disease than it should be that he has had to be treated for any other complaint in the wards of a general or special hospital. Another point to be remembered is that certificates of lunacy are not so often meant for the protection of society from the lunatic as for the safety of the patient from the machinations of his friends. The lunacy laws were framed for the protection of people against evils some of which apparently are in the near possibility of a revival—we refer to the increasing fashion of treating in "homes" people who are undoubtedly insane. These "homes" are not under supervision of any kind and there seems to be no guarantee that abuses of the very sort that certificates were devised to render impossible may not re-arise because of the shrinking of over-sensitive people from the term "certificate of lunacy." It is of good augury that such enlightened and new measures as treatment in or by general hospitals should be strongly advocated, but it is simply self-deception and false kindness to assume that it is always possible to dispense with certificates. Whether the cause of the insanity be central or bodily the symptoms may

CASE 34.—A single woman, aged 28 years, whom I saw with Dr. J. Altham and Dr. J. Graham of Cockermouth, had suffered from spasms for years. For 25 weeks colic and jaundice had been present. On July 24th, 1900, duodeno-choledochotomy had been performed, when three stones were removed. The wound healed, but it reopened after an attack of pain followed by rigor. The patient returned on July 6th, 1901, suffering from jaundice, and there were a biliary fistula and infective cholangitis. Choledochotomy was performed on this date, one gall-stone being removed. The biliary fistula was excised and a good recovery ensued, the patient being well in November, 1901, except for a small sinus, not biliary.

CASE 35.—A woman, aged 30 years, was seen by me with Dr. F. C. Sprawson of Blackpool. Cholecystotomy for gall-stone colic followed by jaundice had been performed in February, 1900, by a surgeon since deceased. There was a biliary fistula, with jaundice if the fistula was not kept patent. Choledochotomy was performed on July 20th, 1901, when one stone was removed from the common duct. Cholecystotomy was also carried out, the case ending in a good recovery, and the patient was well in November, 1901.

CASE 36.—The patient, a woman, aged 38 years, had a history of spasms, infective cholangitis, and jaundice extending over some years. There were high temperature and incessant vomiting for a week before operation. The patient was extremely feeble. There were infective cholangitis, vomiting, heart disease, and deep jaundice. Choledochotomy was performed on July 21st, 1901, and several stones were removed from the common duct, but death from shock and heart failure resulted. The patient took ether badly, becoming very livid and almost pulseless.

CASE 37.—A man, aged 40 years, whom I saw with Dr. C. H. Taylor of Derby, had had indigestion and pain for a year. There had been loss of weight and deep jaundice for five weeks. There were five stones in the common duct and 35 in the gall-bladder. Choledochotomy and cholecystotomy were carried out on July 30th, 1901. Lumbar drainage was employed. The patient went home with a small tube in the sinus. He had lost his jaundice and otherwise was well in January, 1902.

CASE 38.—The patient, a single woman, aged 45 years, was seen by me with Dr. N. Williams of Harrogate. There had been gastric ulcer for two years. Colic and jaundice were present. There was loss of weight and of strength. There was pyloric stenosis with dilatation of the stomach. There were 20 gall-stones in the gall-bladder and two in the common duct. Choledochotomy, cholecystotomy, partial cholecystectomy, and pyloroplasty, which were carried out on August 5th, 1901, resulted in a good recovery, and the patient was well in November, 1901.

CASE 39.—A man, aged 46 years, was seen by me with Dr. R. H. Luce of Derby. For four months colic and jaundice had been present and there was loss of weight. The jaundice was very deep indeed. There were one stone in the common duct and two stones in the gall-bladder. The pancreas was swollen. Choledochotomy and cholecystotomy were performed on August 8th, 1901. Lumbar drainage was employed. The patient was well in November, 1901.

CASE 40.—I saw this patient, a man, aged 62 years, with Dr. J. Lawrence of Darlington. For two years colic had persisted and for a year jaundice had been present. Loss of weight to the amount of five stones was complained of. Cholecystenterostomy had been performed previously by another surgeon with temporary improvement. Relapse and recurrence of jaundice with great loss of flesh and of strength had taken place. Jaundice was present; there were three stones in the common duct and many in the gall-bladder, and there was cancer of the head of the pancreas. Choledochotomy and cholecystotomy were performed on August 8th, 1901. Anterior drainage was adopted. The patient was relieved of the pain and jaundice and he returned home within the month. Gradual loss of strength due to cancer of the pancreas ended in death in October, 1901.

CASE 41.—A single woman, aged 50 years, seen by me with Mr. J. C. Wilson of Haworth, had had spasms and jaundice for years. There were ague-like attacks, loss of flesh, infective cholangitis, and jaundice. There were one stone in the gall-bladder and five stones in the common duct. Choledochotomy and cholecystotomy were proceeded with on Sept. 1st, 1901. Lumbar drainage was employed. The patient was well in November, 1901.

CASE 42.—The patient, a woman, aged 47 years, was seen by me at the General Infirmary. For five years she had suffered from colic and jaundice with ague-like seizures. The jaundice was intensified after each attack. Choledochotomy and cholecystotomy, performed on Sept. 17th, 1901, resulted in a good recovery and the patient was well in December.

CASE 43.—A married woman, aged 38 years, was seen by me at the General Infirmary. She had suffered from colic from February to June, 1900, with jaundice and signs of suppuration. Cholecystotomy and draining the abscess between the gall-bladder and the intestine had been carried out. Some gall-stones had worked back from the common duct. There was colic again two months later, with persistent jaundice and infective cholangitis. Choledochotomy and cholecystotomy were performed on Sept. 27th, 1901. One stone was removed. A good recovery followed and the patient was well in December, 1901.

CASE 44.—I saw the patient, a man, aged 51 years, with Mr. W. C. D. Hills of Upwell, Wisbech. There had been slight colic but deep jaundice for a year and great wasting. There was infective cholangitis. There were five stones in the common duct. Choledochotomy was performed on Sept. 29th, 1901. The duct was drained and a lumbar drain was also used. There was chronic pancreatitis. The patient was very well and he had gained one stone and three pounds in weight in November, 1901.

CASE 45.—The patient, a man, aged 53 years, who was seen by me at the General Infirmary, had had colic for 12 years and jaundice for two years. There was deep jaundice. On Oct. 10th, 1901, choledochotomy was performed and a stone was removed. The patient was well in December, 1901.

CASE 46.—A man, aged 58 years, was seen by me with Dr. C. S. A. Rigby of Preston. He had had very deep jaundice for three years. Biliary cirrhosis and ascites as well as jaundice were present. There was a stone in the common duct. There were cirrhosis of the liver and ascites. On Oct. 21st, 1901, choledochotomy was performed. The omentum was fixed to the anterior abdominal wall. Anterior drainage was employed. In December, 1901, I had a letter to say that he was regaining strength and feeling well.

CASE 47.—The patient, a woman, aged 46 years, was seen by me at the General Infirmary. There was a history of spasms years before, and for the last eight months there had been very little pain but the temperature rose to from 103° to 105° F. every night. Jaundice and infective cholangitis were present. Choledochotomy was performed on Nov. 7th, 1901. The temperature dropped to normal on the day of operation and remained normal. The patient is now well.

CASE 48.—The patient, a single woman, aged 52 years, was seen by me with Mr. C. Brook of Lincoln. There had been spasms for years and jaundice for four months. The pancreas was large. There were 65 calculi, including 18 in the common duct. Choledochotomy and cholecystotomy, performed on Nov. 30th, 1901, resulted in a good recovery.

CASE 49.—I saw the patient, a man, aged 48 years, at the General Infirmary. He was a stout, unhealthy subject, with a history of former intemperance. He had suffered from gall-stones for 20 years and from jaundice with infective cholangitis since May, 1901. On Dec. 7th, 1901, choledochotomy was performed. 126 gall-stones were removed from the gall-bladder and 88 from the common and hepatic ducts. Recovery was retarded by bronchitis, but the patient was discharged well in five weeks.

Duodeno-choledochotomies.—Seven cases (Cases 50 to 56, inclusive) operated upon before 1900 with five recoveries have been previously reported.

CASE 57.—A married woman, aged 34 years, was seen by me with Mr. G. E. Coleman of Hemsworth. For many years she had had colic. There was intermittent jaundice. Cholelithotrity had been performed in February, 1891, and the patient was well in 1896. Then came recurrence of pain with jaundice and ague-like attacks. Dense adhesions rendered operation very difficult. Only débris came away. The pancreas was large. On July 23rd, 1900, duodeno-choledochotomy was performed. The gall-bladder was drained, but no lumbar drain was used. The patient died on the sixteenth day from exhaustion due to a leaking duodenum.

CASE 58.—I saw this patient, a single woman, aged 28 years, with Dr. Altham and Dr. J. Graham of Cockermouth. She had suffered for 25 weeks from colic and for 14 weeks jaundice had been present. The gall-bladder was distended and there was one stone in the cystic duct, while two were removed from the common duct by the duodenal route. The wound healed, but it reopened upon an attack of pain be the same both in intensity and duration; and we are at one with Dr. CHARLES MERCIER in his letter which we published last week, wherein he protests against "the view that insanity is a thing apart, a specific entity," having no community of nature with what Dr. RAW classifies as temporary aberration of mind. And although insanity due to bodily causes may not be so detrimental to the prestige of the family as when the cause is due to breakdown in the central system, it is nothing but a sickly sentimentalism that would refuse to extend to the former the security afforded by the law. The present outcry against certificates is partly the result of reaction against a process which has been too freely resorted to and partly follows on a better appreciation of the pathology of insanity; but there are occasions when asylum treatment under certificates is a blessing and not a curse. It ought to be regarded as a sanitary quarantine in the interests of all parties.

◆

The Seed and the Soil.

WITH the discovery of pathogenic micro-organisms the views with regard to infection and intoxication which had previously been held underwent very considerable changes. Formerly, the term "infective diseases" was understood to denote those maladies which were caused by certain poisons or noxious bodies which either entered the body from without or were manufactured in, or by, the tissues of the diseased person. The investigations which have been made as to the properties and mode of action of the bacillus of tuberculosis offer a good example of the influence which has been exerted on the minds of medical men by the discovery that certain diseases are caused by living germs. The description of that bacillus by Professor KOCH in 1882 and the proof of its causal relationship to the disease naturally led to great modifications in the treatment of pulmonary tuberculosis, the object of the many investigators, who at once set to work, being to search for means to destroy the bacilli which were causing the destruction of pulmonary tissue. Although 20 years have elapsed since that time no direct germicide has been found which will destroy the germs within the lungs without injury to the host. Nevertheless, a form of treatment has been introduced which promises hope of success, not by directly killing the bacilli but by rendering the tissues unfavourable to their growth. In other words, since bacteriology has become a recognised branch of medical science too much attention has been directed to the germs themselves and not sufficient to the soil in which they grow.

To this aspect of diseases caused by micro-organisms attention has been prominently called by two addresses which have been published in our columns. Dr W. HOWSHIP DICKINSON, in delivering the Baillie Lecture at St. George's Hospital, gave an eloquent address with the "parable of the sower" as a text.[1] He reminded his hearers that the distribution of plants within the range of the seed is regulated by the local conditions which the seed meets with—soil, moisture, temperature, light, and what not. Of course there is no growth without the seed and an infectious disease cannot attack an individual without the pathogenic organism becoming engrafted in his tissues. "*Omne vivum ex ovo* holds good now as in the time of HARVEY. But the seed may be indiscriminately and widely spread; within certain wide boundaries it may often be said to be ubiquitous, so that the whole question of distribution turns not upon the seed but the soil, not upon the germ but its reception." Dr. DICKINSON also instanced the resistance to infection as shown by medical men when he remarked, "Many of us—I may even say most of us—are frequently exposed to infection without being infected in virtue of the unproductiveness of the soil in which the seed falls. Some persons are prone to succumb as others are to resist." There are undoubtedly conditions of the body, both of blood and of tissue, which predispose to the entertainment or to the rejection of certain infective diseases. These conditions, which are sometimes included in the term "second etiological factor," have not been fully ascertained and considerable diversity of opinion exists in regard to them. There has been recently a marked tendency to discount the power of heredity; for example, in reference to tuberculosis the importance of family history is seen to have been much exaggerated. Certain authorities maintain that infection exerts a much stronger influence than does heredity, and modern research tends to confirm this view. Certainly heredity alone cannot cause the disease but the same is the case with the pathogenic bacillus, otherwise the human species would long ago have become extinct. But heredity prepares the soil for the favourable reception of the seed. Dr. STEPHEN MACKENZIE in the annual oration of the Medical Society of London delivered in May of this year[2] also dwelt upon the same subject and maintained that there was no doubt that the progeny of the tuberculous are much more liable to tuberculosis than are those in whose family no such strains run. On what conditions that predisposition depends there is no absolute knowledge. It is also a fact, however, that if every means is taken to improve the general condition of individuals thus weakened by inheritance—that is to say, if healthy surroundings are provided and measures for developing the chest and increasing the expansion of the lungs are adopted—the resistance against the inroads of the bacillus may be greatly strengthened. Dr. MACKENZIE extended his remarks to a consideration of the natural resistance to influenza, rheumatic fever, and appendicitis. With regard to the last-named disease, much information has been obtained within recent years. Peculiarities of position and anatomical formation of the appendix and its mesentery tend to produce contortions and contractions and interference with the circulation in the appendix which prevent the discharge of its secretions, favour the formation of fæcal concretions, and check the expulsion of foreign bodies accidentally entering its canal. In one of these ways the vitality of this portion of the intestinal tract becomes impaired. The organisms in the appendix find a medium which enables them to grow and to multiply, so producing inflammation and its attendant results. The soil is pathologically prepared for the virulent growth of the seed; examples of analogous conditions will occur to all our readers.

In dealing with diseases caused by micro-organisms there has been a tendency to overrate the power of the infective agency. This tendency in the routine of modern medicine, which most of us admit to be unfortunate, can be mentioned without belittling the faithful and splendid work of bacteriologists who number among them some of the foremost scientific men of the day. Indeed, we may say that it is the excellence of their achievements that has led to the position, for their aid has been so powerful that an inclination has been created to leave everything to them. But bacteriologists naturally regard disease mainly from a laboratory standpoint. Their investigations have produced results which can scarcely be over-estimated, especially in regard to prophylaxis, but it is for the medical practitioner to regard the natural resistance against disease, possessed by every human being to a greater or less extent, as of equal or even greater importance than the infective agents. It is the physician's duty to heal and as we have shown, for purposes of treatment, the care of the soil has very often a more practical result than the attempted destruction of the seeds.

Annotations.

"Ne quid nimis."

THE KILLED AND WOUNDED IN CIVIL LIFE.

IN spite of several Acts of Parliament, each one more or less admirably drafted, accidents in British factories and workshops are of hourly occurrence. It is probable that the man in the street has no notion of this. He possibly imagines vaguely that now and again an employé may meet with an injury but were he to be told that during each hour of every working day about 12 people engaged in the production of trade material sustain injuries of one sort or another it would, no doubt, shock him considerably. That soldiers should be killed or suffer wounds in battle is inevitable, yet after each publication of casualty lists the national heart bleeds afresh. Casualty lists of the killed and wounded in civil life are published only once a year, in the annual report of the Chief Inspector of Factories and Workshops. Last year there were 83,760 non-fatal accidents and 1035 accidents which ended fatally. In 1900 the numbers respectively were 77,975 and 1045. It is not too much to say that the whole of these so-called accidents are avoidable. No doubt many of them are due to carelessness or negligence on the part of the victims, but it cannot be denied that some are caused by defective or worn-out machinery and appliances.

OPHTHALMOLOGY AT OXFORD.

OUR readers will find in our columns this week another example of the good fortune that is at present attending Oxford. Its time-honoured university has scarcely recovered from the shock of the noble gift of the Rhodes scholarships before a benefactor, Mrs. Margaret Ogilvie, who in after years will be styled "of pious and blessed memory" but who is at the present moment fortunately able to see and to appreciate the good results of her liberality, has presented to it a sum of money yielding a yearly income of £200 at least for the maintenance of a readership in Ophthalmology. This gift the University has accepted with great alacrity and gratitude, especially as it is weighted with few conditions and will draw nothing from the University chest. The intention of the generous donor is primarily to encourage the prosecution of original research in the department of ophthalmology and secondarily to provide instruction in diseases and defects of the eyes and their treatment for members of the University of Oxford and for legall qualified members of the medical profession. With this en in view systematic and clinical lectures as well as demonstrations are to be given. The reader is to be chose by a board of eight members most of whom occupy a official position in the University, whilst others are connected with the Oxford Eye Hospital, and one is th President of the Royal College of Surgeons of England The duties with which the Margaret Ogilvie's Reade in Ophthalmology, as he is to be termed, is intereste are to deliver without fee 12 lectures during the University academical year to all legally qualified medica men, at least six of which shall be systematic, whils the remainder may at his option be clinical. He i to devote himself to, and to conduct original researc upon, the pathology and therapy of diseases of the eye an to furnish a yearly report to the Board of the Facult of Medicine giving in detail the result of his investigations. He must retire at the age of 60 years except by the special grace of the electoral board which is empowered to grant him five years' additiona tenure of the office and no more. He must be honorary su geon to the Oxford Eye Hospital, and if the honorary surgeo declines to accept the readership no appointment is to b made, but the yearly interest is to be added to the capita sum. Finally, he must reside for 30 weeks in each year i Oxford or within a mile and a half of its centre, Carfa For his salary he is to receive three-fourths of the interes on the capital sum and the proceeds of a capitation fe of £2 on the medical students whom he can attract t his lectures. The remaining fourth of the interest i to be spent on supplying apparatus, diagrams, and othe requisites for research in ophthalmology and for pu poses of instruction. The first holder of the office the Margaret Ogilvie Readership in Ophthalmology is M Robert Walter Doyne, F.R.C.S. Eng., of Keble Colleg We congratulate Mr. Doyne on his appointment an trust that he may long retain it. He has distinguishe himself in various ways and is a man endowed wit much originality and power of research. He must, are sure, feel that his labours will constitute a precedent f his successors and that he should spare no effort to rend the office worthy of the place it will hold, both at home a abroad, as a great centre of ophthalmological research England. On the physical side of optics he has the adva tage of easy communication with the most learned a experienced physicists, whilst in the Oxford Eye Hospital has abundance of material ready to his hand for investig tion. Many points in the pathology and treatment the diseases of the eyes are uncertain and obscure a it is only by the patient observation and the leisure th can be obtained in such a university as Oxford that some these problems can be elucidated. In the meanwhile shall watch with interest the results that will be obtain from Mrs. Margaret Ogilvie's generous effort to establi ophthalmology on a sound and broad basis in Oxford and take the opportunity of recommending her action to othe who are possessed of large or small accumulations of weal as one that is highly commendable and worthy of imitation

THE DEPTH OF SLEEP.

AN interesting communication on the depth of sleep normal individuals and in psychopathic persons is co tributed by Dr. Sante de Sanctis and Dr. U. Neyroz to t *Psychological Review* for May last. Previous observers had made use of auditory stimuli or sounds of definite degrees of loudness to determine the depth of sleep from which the sleeper could just be awakened and this was the method adopted by Kohlschütter, Michelson, and others. Dr. de Sanctis and Dr. Neyroz adopted the method of tactile and pressure stimuli, using for this purpose æsthesiometers with both sharp and blunt points, the pressure of which could be nicely regulated to a degree just sufficient to cause awakening. The experiments made on any one person lasted over a period of about six consecutive months and were carried out at different hours on successive or irregularly alternating nights. Four of the persons studied were normal subjects and five were psychopathics affected with some form of nervous disorder. As the result of many thousands of separate observations made and carefully collated and plotted into the form of "curves of sleep" it appeared that the maximum depth of sleep was attained within one and a half hours of falling asleep and generally in the third half-hour, after which the curve of sleep became shallower. Hourly oscillations in the depth of sleep occurred thereafter with a maximum and a minimum for each hour, the curve, however, descending on the whole for a while until a second deepening of sleep occurred. This "secondary deepening" lasted about one and a half hours and occurred during the middle period of the total duration of sleep. In all the five pathological subjects the depth of sleep was far greater than in normal persons. These included three epileptics, one paralytic, and one "degenerate" or feeble-minded patient. It was also found—contrary to the common belief that neuropathics and epileptics were light and restless sleepers—that sleep was very deep in the majority of cases (60 per cent.) of epilepsy with the classical symptoms of *haut mal*. The curves of sleep, however, differed much more among abnormal than normal subjects. In the course of the investigation it was also found that dreams occurred in every period of sleep and even in the earlier hours when the depth of sleep was greatest, but they were more frequent and more vivid in the later hours of sleep, especially towards morning. The "dream activity" of psychopathic persons was slight as compared with normal subjects and the memory of them was also less marked or definite.

LUNACY IN SCOTLAND.

THE forty-fourth annual report of the Commissioners in Lunacy for Scotland states that the number of insane persons in Scotland under official cognisance was 16,288 on Jan. 1st, 1902, as compared with 15,899, which was the corresponding figure for the previous year. An increase is thus apparent of 389 insane persons during the year 1901. These figures do not take account of insane persons maintained at home by their natural guardians, as no official returns are made of such persons. Since 1858 the number of lunatics under the jurisdiction of the Board of Commissioners has increased 180 per cent., whereas the increase of the population of Scotland during the same period has been 49 per cent. The proportion of lunatics to the general population shows that the increase has been a steady one. Thus for every 100,000 of the general population there were 302 lunatics in 1890, 324 in 1895, 347 in 1900, 349 in 1901, and 353 in January, 1902, and this increase seems to hold good for both private and pauper patients. The number of patients admitted during the year to all institutions amounted to 3500, comprising 538 private and 2962 pauper patients. Of this total 1771 were males and 1729 were females. The number of patients discharged as recovered during the year amounted to 1495, or 11·5 per cent. of the average number resident in all establishments. The deaths during the year amounted to 1087, or 8·4 per cent. as calculated on the same basis. Of the deaths 20 were due to suicides and accidents, 63 to epilepsy and convulsions, 84 to apoplexy and paralysis, 95 to senile decay, 137 to phthisis, 147 to cardiac disease and its complications, 167 to general paralysis of the insane, and the rest to other causes. Among the cases of general paralysis which ended fatally during the year 136 patients were males and 31 were females. The various institutions for patients include seven Royal or chartered asylums established prior to the Lunacy Act of 1857, 16 district asylums created under the provisions of the said Act, three private asylums, lunatic wards licensed by the board to receive pauper patients and forming part of 15 poorhouses, two institutions for imbecile children, and the lunatic department of the General Prison at Perth for the accommodation of insane prisoners and convicts. In connexion with the subject of the increase of pauper lunacy during the past two decades, a point to which attention had been from time to time directed in former reports, the Commissioners publish a detailed account of the conditions prevailing in the island of Lewis in Ross-shire, a district which does not form part of any great commercial or industrial area and is not much affected by such disturbing factors as immigration or emigration. The statistics of this locality for the past 20 years show a very considerable increase of pauper lunacy, apparently *pari passu* with a corresponding growth of pauperism in the district. The Commissioners are of opinion that many persons in the district referred to are now recognised as lunatics and sent to the asylum for treatment who would not have been so recognised and treated 20 years ago. This change, though it has been in operation longer in other parts of Scotland than in Lewis, is "believed by the board to account for the general growth of pauper-lunacy in Scotland. It has its chief source primarily in the more widely-spread desire to look to the parish as bound to provide for the mentally defective members of a family and in the increased willingness of parish councils to recognise such claims." Regarding the cost of maintenance and other expenses connected with the reception and care of patients, it appears that the average annual cost per head was £43 4*s*. 9*d*. for all district asylums. The expenditure per head on pauper lunatics is recognised as having steadily increased since 1895 owing to increased cost of maintenance and of land and buildings. A supplementary report on the dieting of pauper lunatics in Scotland by Dr. J. C. Dunlop has also been issued by the board, and an account of it appeared in THE LANCET recently.[1]

CANCER RESEARCH IN THE UNITED STATES.

THE second annual report of the Cancer Committee to the Surgical Department of the Harvard Medical School was published in a series of articles in the *Journal of Medical Research* for May. The findings of the committee, which were the results of painstaking investigations of a year's duration, were decidedly antagonistic to the parasitic theory of the origin of cancer. The conclusions reached were summarised by Dr. Edward H. Nichols, demonstrator of surgical pathology at the Harvard Medical School, as follows. It has been claimed by the adherents of the theory of the parasitic origin of cancer that (1) a proliferation of epithelial cells analogous to the lesions seen in cancerous *tumours* can be produced by certain well-known protozoa (nodules caused by the coccidium oviforme), (2) certain skin lesions characterised by epithelial cell proliferation are due to the action of a so-called protozoon (molluscum *contagiosum*); (3) blastomycetes are constantly present in human cancers and are the cause of the lesion; (4) by experimental inoculations of animals with "blastomycetes" true epithelial or cancerous nodules can be produced, and (5) finally, the well-known endocellular bodies seen in the protoplasm of cancer cells have a definite morphology; these are the "parasites" and the supposed cause of cancer. The results of the work pursued by the investigators lead them to these conclusions: (1) the lesion produced by the coccidium oviforme is essentially a process of chronic inflammation and is not analogous to the lesion seen in cancer; (2) the lesion in molluscum contagiosum is characterised by certain changes in the epidermis, is not due to the action of a protozoon, and is not analogous to cancer; (3) the so-called "blastomycetes" ("saccharomycetes") of Sanfelice and Plimmer are torulæ; (4) the lesions produced by these "blastomycetes" (torulæ) are essentially nodules of peculiar granulation tissue, and are not cancerous or in any sense true "tumours"; (5) blastomycetes are not constantly present in human cancers; and (6) the peculiar bodies seen in the protoplasm of cancer cells are not parasites or the cause of the lesions, but probably are in part at least atypical stages of the process of secretion by glandular epithelium.

THE METROPOLITAN WATER-SUPPLY.

THE report on the condition of the Metropolitan Water-supply during the month of April last has recently been issued by the Water Examiner appointed by the Local Government Board. The Thames water at the intakes of the companies was in good condition during the whole of the month. The height of the Thames varied from three inches above to nine inches below the average summer level. The average daily amount of water abstracted from the Thames was 117,263,936 gallons, from the Lee 44,641,921 gallons, and from springs and wells 44,266,786 gallons. The daily total amount of water distributed was 206,428,613 gallons for an estimated population of 6,349,333, and this represents a daily consumption per head of 32·51 gallons. This estimate, it may be remarked, entirely ignores the quantity of water used for manufacturing and other trade purposes. So that the daily consumption per head is really considerably less than the amount stated in the report of the Water Examiner. According to the calculation of the engineer to the East London Waterworks Company, the approximate amount of water used for other than domestic purposes is no less than 30 per cent. of the total quantity delivered. During the month of April last three of the metropolitan companies—the Chelsea, the East London, and the Kent—distributed a smaller quantity per head to their customers than they did during the corresponding month of the year 1901. The other five companies distributed a greater quantity. The metropolitan company which during April, 1902, gave the largest average daily supply per head was the Chelsea Company (39·63 gallons) and the company which gave the smallest average daily supply per head was the East London Company (26·93 gallons). The amount of water which is now obtained from wells is considerable. Of the total quantity distributed during the month that derived from springs and wells was no less than 21·444 per cent. The Chelsea, the Grand Junction, the Lambeth, and the West Middlesex companies have no wells. The East London Company on an average pumped daily 8,455,000 gallons from wells and 1,372,000 from Hanworth "springs." The Kent Company pumped daily an average quantity of 18,079,701 gallons from wells. It would be instructive to know the amount obtained from each well, but we are not aware that the Water Examiner has ever made any attempt to obtain this information. The New River Company distributed daily an average amount of 14,131,353 gallons of filtered water derived from springs and wells, 913,732 gallons of unfiltered spring and well-water, and 255,970 gallons derived from the Hampstead and Highgate ponds. The Southwark Company pumped daily from their Streatham well an average quantity of 1,297,000 gallons. Dr. T. E. Thorpe, F.R.S., the analyst appointed by the Local Government Board, reports that organic carbon was present in the samples of water analysed by him in proportions ranging from 0·040 to 0·225 units in every 100,000 units of the water distributed by the companies. The proportions of brown tint observed in a two-foot tube, ascertained by their comparison with the standard tint usually employed, ranged from three degrees to 20 degrees. The water supplied by the Lambeth Company exhibited the deepest average tint of brown. The Water Examiner states that "all the samples of water collected at the works of the companies were efficiently filtered." He, however, gives no authority for this statement, nor is there any evidence in the report to show that the Government analyst has ever at any time made any analysis of water collected at the works of any company. The following table, which corresponds with some of those recently published, gives the most important results of the full analyses made by Dr. Thorpe of one specimen of water distributed by each of the metropolitan companies:—

Results of Analysis expressed in Parts per 100,000.

Company.	Date and place of collection of the specimen.	Organic carbon.	Organic nitrogen.	Nitrogen as nitrates and nitrites	Total combined nitrogen.	Chlorine.

RELIGION AND QUACKERY.

WE have before us a singular advertisement which has been forwarded by a correspondent who has taken it from the *Catholic Times*. It emanates apparently from Buckfast Abbey, Buckfastleigh, in the county of Devon, an institution which the "Catholic Directory" shows to have been founded within the last 20 years and to be under the charge of a prior and nine or 10 members of the Order of St. Benedict who mostly bear foreign names. The advertisement in question proclaims the merits of the "Buckfast Abbey Remedies, all prepared by the Benedictine Monks of Buckfast Abbey, Devon," and in no way differs in language and appearance from other advertisements of quack medicines that are put forth in newspapers for the attraction, rather than for the benefit, of the credulous. Our surprise at its appearance is caused by its purporting to emanate from a body which professes to be formed of religious men whose care for the souls of their fellow-men should not be adulterated with the desire to make money out of their bodily ailments. We recommend the Bishop of Plymouth, in whose diocese the "Abbey" in question is presumably situated, to consider whether its monks are consulting the dignity of their order and their religion in their laudation of the "Buckfast Abbey Tonic," the "Buckfast Abbey Tonic Pills," the "Buckfast Abbey Salve," the "Buckfast Abbey Antibilious Pills," and the "Buckfast Abbey Antipyretic Liniment." To criticise a single "remedy" only in detail, we may point out that the salve is declared to "cure" among other things "cancerous wounds, carbuncles, tumours, scrofulous sores, and similar diseases." Cancer and tumours, if they exist, are not things to be played with, and one of the worst of the many bad results that attend the unrestricted sale of quack nostrums is that they cause delay in the seeking of surgical and medical aid. We invite the bishop to whom we have referred and the heads of the order which seems to be responsible for these paragraphs to inquire carefully whether the terms in which the goods offered are recommended are justified by the nature of the goods themselves. If not the buyers are deceived and the sale becomes a questionable transaction in which more than dignity and decency is involved. Public opinion may to some extent excuse the advertisement of the ordinary quack as venial puffery of his wares. We regret that it should do so but the ordinary quack does not advertise pills and liniments, salves and tonics with notice that they can be obtained from a "Reverend Procurator" at an abbey. If the Benedictine order really sanctions the appearance of advertisements of this class we can only say that it would do better to confine its commercial dealings to the manufacture and sale of its well-known and highly-esteemed liqueur.

UNILATERAL OCCURRENCE OF KERNIG'S SIGN AS A SYMPTOM OF BRAIN DISEASE.

IN 1883 Kernig described a sign of meningitis which has been named after him: when the thigh is extended the hamstring tendons are relaxed, but when the thigh is flexed the leg cannot be extended beyond 135° in consequence of rigidity of the hamstring muscles. The frequency of Kernig's sign in meningitis has been confirmed by many observers. Dr. Roglet[1] found that it could be elicited easily in 85 per cent. of the cases, whether the meningitis was meningococcic, pneumococcic, streptococcic, or staphylococcic. In tuberculous meningitis it is less frequently found. Spinal meningitis is not necessary for its production. But it may occur in other cerebral affections—e.g., hæmorrhage.[2] Several explanations of the mechanism of Kernig's sign have been put forward. The most satisfactory of these seems to be Chauffard's view that the rigidity is due to an exaggeration of the normal tonicity of the hamstring muscles and is analogous to retraction of the head in meningitis. In the *American Journal of the Medical Sciences* for May Dr. Joseph Sailer has recorded a case in which Kernig's sign was unilateral and which so far appears to be unique. A male, aged 20 years, was admitted to hospital on Sept. 16th, 1901. He was partially delirious and complained of severe headache and pains all over the body. For two weeks he had had pain in the side, backache, and headache. On Sept. 14th he went home from work complaining of intense headache and soon became delirious. Next day he was acutely delirious and the head was retracted. The temperature was 104° F. The left arm was strongly flexed and rigid. The reflexes were not exaggerated. Kernig's sign was readily elicited in the left leg. The right leg could be extended in an almost straight line with the thigh when the latter was fixed at right angles to the abdomen. There were numerous subcrepitant râles at the bases of both lungs and slight increase in vocal resonance at the left base. The urine contained albumin and blood and granular casts. On Sept. 18th he was worse. When roused there was lagging of the movements of the left upper eyelid. The mouth was drawn to the right and the right side of the face was wrinkled while the left was smooth. Next day the head was turned to the left and the left pupil was smaller than was the right. There was marked flexor spasm in the left arm which seemed to be paretic. The knee-jerks were slightly increased and Kernig's sign was found in the left leg. On the 20th the head was turned strongly to the left and the left arm was firmly flexed. The right leg was not moved voluntarily. In the left leg occasional irregular movements occurred and Kernig's and Babinski's signs were both obtained. A systolic murmur was heard most distinctly at the cardiac apex. A purpuric eruption appeared all over the body and involved the conjunctivæ and mucous membrane of the mouth. The staphylococcus aureus was found in the blood in pure culture. Death occurred on the 21st. The necropsy showed ulcerative endocarditis of the aortic valves, cloudy swelling of the kidneys, congestion of the cerebral meninges and a softened area in the left motor region, and old osteomyelitis of the left tibia. The staphylococcus aureus was cultivated from the brain. Dr. Sailer suggests that the staphylococcus was latent in the tibia and thence invaded the body. In this case there was unilateral spastic paresis from the cerebral softening. The spasticity did not produce rigidity of the hamstring muscles when the thigh was extended but did when the thigh was flexed, giving rise to Kernig's sign.

A MEDICAL STAFF COLLEGE.

IT will be remembered that the last of the general recommendations of the report of Mr. Brodrick's committee, appointed to consider the reorganisation of the Army Medical Service, strongly suggested the establishment of a military hospital and medical staff college for the training of officers of the Royal Army Medical Corps. The report recommended that steps should be taken by the Advisory Board as soon as it was constituted to present a detailed scheme for the establishment of such a hospital and staff college for the consideration of the Secretary of State. No time has been lost in commencing this reform, though necessarily an interval must elapse before the arrangements are completed. We are informed by the War Office that the next session of the Army Medical School will be held in London and it is understood that the laboratories of the Royal Colleges on the Embankment will be temporarily at the disposal of the Royal Army Medical Corps.

SCLEROSIS OF THE SUPERFICIAL VEINS OF THE LIMBS.

WIDESPREAD sclerosis of veins at all comparable to arterio-sclerosis appears to be unknown; but a few cases of sclerosis of the superficial veins of the limbs have been described by French writers. At the meeting of the Société Médicale des Hôpitaux of Paris on May 9th M. A. Souques and M. Janvier described the following typical case of the latter condition. A labourer, aged 40 years, who had not suffered from syphilis but was addicted to alcohol, came under observation. There was incipient bilateral pulmonary tuberculosis. The superficial veins of the lower limbs were symmetrically indurated. The internal saphenous vein could be palpated from the internal malleolus to the groin, and the external saphenous from the ankle to the thigh. These veins were smaller than normal, hard and resistant, and rolled under the finger like a cord. They were uniformly indurated without any nodulation. In the upper limbs the condition was also symmetrical. Almost all the superficial veins of the arms and forearms were indurated and presented the same characteristics as those of the lower limbs. The veins of the trunk, the neck, and the head were not affected. The induration appeared to have come on gradually and the patient was not aware of its existence. It had not caused any appreciable symptoms. The radial arteries were hard but the temporal arteries were not tortuous. The heart was normal and the urine did not contain albumin or sugar. This case is remarkable in consequence of the extent of the venous induration, its perfect symmetry, its localisation in the superficial veins of the limbs, its latent character, and the obscurity of the etiology. M. Letulle, who has studied the anatomy of venous sclerosis in two cases, points out that the lesions differ from those of chronic phlebitis. The indurated vein is like a contracted artery, its lumen is narrowed and scalloped, and the folds formed by the thickened intima are free from clots. The pathology of venous sclerosis is obscure; some have suggested that it is similar to that of arterio-sclerosis.

A MARRED LANDSCAPE AND A SULLIED AIR.

Cement works in many parts of our most picturesque country—for they are necessarily situated in river valleys—are defiling the air to an appalling extent. Plant life is suffering, tree foliage is being blighted, and the formerly charming vistas of vale and down are now frequently heavily curtained with a malodorous and noxious fume. The best examples of this vandalism occur perhaps along the valley of the Medway in one of the most delightful parts of the county of Kent and that part of it which was so dear to the author of the "Pickwick Papers." The locality of the mischief and offence is, of course, dependent upon the direction in which the wind is blowing. If there is little or no movement in the air the works themselves are buried in a sickly gloom. We cannot believe that this evil, which is assuming very wide-spread dimensions, is inseparable from the process or that it is not amenable to treatment. It used to be said that the smoky chimney of the factory was something that admitted of no remedy. We now know that by bringing a little pressure to bear upon the offenders the smoke nuisance has been very considerably diminished. We urge that similar pressure should be brought to bear upon the manufacturers of cement, for we are convinced that, like the smoke nuisance, the offensive fumes of the cement works chimney could also be effectually dealt with. Moreover, there is a provisional order in the Alkali Works Regulation Act of 1881 to the effect that an inspector may from time to time inquire whether in any works in which aluminous deposits are treated for the purpose of making cement—i.e., cement works—means can be adopted at a reasonable expense for preventing the discharge from the furnaces or chimneys of such works into the atmosphere of noxious or offensive gases. Judging from the numerous cement works throughout the country, all of which belch forth unchecked huge volumes of offensive fumes, it is evident that the provisions of this Act are not carried out, because, most probably, the manufacturer has persuaded the authorities that the expense of abolishing the nuisance would not be "reasonable." As is well known, cement is generally made by heating together lime and the mud of river estuaries. In this process there is, as might be expected, a considerable escape of malodorous organic fumes, besides sulphur dioxide and carbon monoxide arising from the coke, and immense quantities of coke are consumed for the purpose. Very definite and concerted action is wanted in this matter in order that this tremendous defilement and disfigurement may be stopped. It is only by vigorous action that manufacturers will be roused to give any attention to the possibility of providing means of abating the nuisance, but we feel sure that chemical engineering is not so backward as to be unable to afford a simple and comparatively inexpensive method of prevention.

A VOYAGE OF EXPLORATION.

In a contribution to the *Archiv für Schiffs- und Tropen-Hygiene* Dr. F. Plehn relates his observations during a recent holiday trip through German East Africa. Owing to a famine which had been raging for three years the districts to the east and north of Tanga, towards Kilimandjaro, were almost entirely depopulated, the greater part of the villages being abandoned. The inhabitants were either dead or had fled for refuge to the coast. It would seem that famines are of frequent occurrence in German East Africa, but Dr. Plehn nevertheless believes in a prosperous future for the colony. What is needed is a system of artificial irrigation. In the elevated hinterland the vegetables of Europe all thrive wonderfully, producing several crops each year. The climate is highly salubrious, malaria being almost entirely unknown. Sites suitable for sanatoriums abound in every direction. Infectious diseases are seldom met with, always excepting small-pox which is endemic, affording a fine field for vaccination. In order to stamp out the disease Dr. Plehn recommends that regular supplies of lymph should be procured from the Hygienic Institute at Cairo, which is under the direction of a German—Professor Bitter. On his return journey Dr. Plehn halted for a time in Egypt in order to investigate the plague. At Alexandria he received valuable information from another German in Government employ—Dr. Gottschlich. According to this observer the mortality from plague is lower in Egypt than in India, not having exceeded 50 per cent. of cases treated. The pneumonic variety is much less fatal than elsewhere, fully one-third of the patients who suffered from it at Alexandria having recovered. Dr. Gottschlich succeeded in communicating plague to mice and rats by means of sputa taken from convalescent plague patients 70 days after their recovery. Dr. Plehn was greatly impressed by the zeal, activity, and intelligence of the medical officers belonging to the Egyptian sanitary department, most of whom, he says, are Germans or Swiss. It was owing to their untiring labours that the plague was prevented from spreading. Finally Dr. Plehn went to Rome to investigate malaria. Here he met Dr. Patrick Manson and became a convert to the mosquito theory. The objections to it which formerly seemed to him so fatal fell to the ground as though by magic before the explanations furnished by his English and Italian *confrères*.

WASTE WATER AND SEWAGE DISPOSAL IN JOHANNESBURG.

A report has recently been presented to the municipality of Johannesburg by Dr. Charles Porter, the medical officer of health, detailing a temporary sewerage scheme for the disposal of slops, bath-water, and the like. There are in Johannesburg 9974 houses, nearly all of which are provided with some kind of receptacle into which slops are thrown and the bath-water is removed from 5900 houses. There appear to be no drain connexions to any dwelling-houses, but the receptacles are emptied and the bath-water is removed three times weekly into two- and four-wheeled tanks holding 400 and 600 gallons respectively, which are drawn by mules in some instances as far as two and a half miles to be emptied into a six-inch sewer which discharges some three and a half miles to the west of the town. There are at present carted daily in this manner about 55,000 gallons of slop-water and 36,000 gallons of bath-water at an approximate cost of nearly £50 or over £15,000 yearly. In addition some 75,000 gallons of waste water enter the main sewer by gravitation or by pumping from the hospital, gaol, and breweries. Dr. Porter estimates that within the next two years there will be about 212,000 gallons of waste water to be dealt with daily, and until a comprehensive system of sewerage is established he recommends the laying down of additional six-inch and twelve-inch sewers with a large number of depositing inlets constructed as lamp-holes or manholes and provided with tightly fitting covers perforated by a pipe with a stop-cock and a coupling to which a hose from the slop tank could be readily attached, thus allowing the contents of the tank to be easily discharged into the sewer without any nuisance being created. The treatment of the sewage advised is by sedimentation in a tank of a capacity of 500,000 gallons, the effluent being treated either by irrigation or over bacterial contact beds. The total cost of the scheme is estimated by the acting town engineer at £50,000 and it could be completed in about nine months.

WE deeply regret to announce the death at the early age of 38 years of Dr. John Wichenford Washbourn, C.M.G., physician to, and lecturer on physiology and bacteriology at, Guy's Hospital. Dr. Washbourn was recently decorated for his services as consulting physician at the Imperial Yeomanry Hospital at Deelfontein and Pretoria. He was one of the most brilliant of the younger generation of London physicians and death cuts short a career of exceptional promise.

THE Midwives Bill was read for the second time in the House of Lords on Friday last, June 20th. Somewhat serious exception to the measure was taken by the Lord Chancellor and other peers, as will be seen from our report of the proceedings. It is probable, therefore, when the Committee stage is reached that efforts will be made to alter the Bill.

SANITATION AT THE COLONIAL NATIVES' CAMP, ALEXANDRA PARK.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

THE establishment of a camp for the colonial contingents on the grounds that surround the Alexandra Palace has given rise to sanitary difficulties presenting special and unusual features. So far as the Europeans are concerned, whether they come from Australia or Canada, their habits and customs are much the same and it is comparatively easy to provide for their needs. But with regard to the coloured natives of the various colonies very unusual requirements have had to be supplied. Thus the Mahomedans will not eat meat unless they have themselves killed the animal to be consumed. With the Indians they must not only kill, they must also themselves cook their food. But the slaughtering of cattle, especially in large towns, is of necessity subjected to certain sanitary regulations. Therefore it has been necessary to build two small slaughter-houses in the grounds. These consist of concrete flooring surrounded by a roofless wooded palisade. The floor is not level but slopes to the centre. After an animal has been slaughtered the concrete floor is scrubbed and washed and the blood and water gravitating to the centre drains into a corrugated iron tank which is sunk into the ground close to, but outside, the palisade. After these operations are terminated a portable pump is brought to the spot and the blood and water are pumped out of the tanks and conveyed away from the palace grounds. Near at hand there is another wooden shanty where the Indians cook the meat in artistically shaped brass saucepans which they place on small and slow fires lighted on the ground, thus preparing their food in their own manner. Very strict orders have to be given to prevent anyone entering, for the Indian will not eat food on which the shadow of the European has fallen. The Mahomedan is not so strict. He only insists on killing the sheep and allows the contractor to cook the meat; but a soldier accompanies the carcass to the kitchen and the cooks have to give their word of honour that they will not change the meat in the process of cooking. All this may seem peculiar, but from the sanitary point of view who shall say that it is not justifiable? Have not the discoveries of modern science, and especially of bacteriology, demonstrated the necessity of a strict inspection of our meat-supply? The Eastern peoples and the inhabitants of the desert have, in this respect, preceded us, and by many centuries.

Again, these coloured people give us a splendid example in respect to personal cleanliness. The Mahomedan may not pray unless he first washes himself, and the greater part of the coloured races, whether Mahomedan or otherwise, are very fond of a good sluice down. But here another difficulty has arisen. Many of these children of the forest or of the desert have no conception of a washing basin. A running brook or a pool of water is their nearest approach to a lavatory, and the idea of contenting themselves with a little water confined within the narrow limits of a basin is quite foreign to their nature. So it was necessary to imitate a running stream with a broad expanse of embankment where any amount of splashing could be allowed. Therefore first an open drain some 30 or 40 feet long was constructed, with a platform about five feet broad gradually sloping towards the drain. Above the drain there are numerous water-taps and tin pails. These latter are big enough for a man to stand in and have water over his ankles just as if he were bathing in a shallow brook. Then he can splash the water over himself and make a splutter to his heart's content. There are several such lavatories in the camp for the coloured contingents and their use has to be divided between the two great parties distinguishing one portion of the native contingents from the other. The first or most highly civilised section is known as the toothbrush party, the other section ignores this symbol of civilisation and does not wash its teeth. We have heard of Whigs and Tories; this, however, is our first introduction to the Toothbrush party.

The greatest difficulty of all, however, has been the providing of closets for the coloured contingent; and as they number some 550 men this was a serious matter. Being unfamiliar with so simple an article of toilette as the washing basin it would have been folly to expect them to understand the intricacies of a water closet with its two-gallon flush, its syphon water seal, and its tendency to get blocked when improperly treated. Therefore, Moule's patent hopper earth closets were provided. But this apparatus possessed all the attractions of a new-found toy. The simple and ingenious mechanism by which a handful of earth is made to fall into the pail was too much for the coloured contingent. Their zeal and love of cleanliness were so keen that they never left the closet till by repeatedly pulling the handle they had emptied out all the reserve of dry earth that the apparatus contained. Thus there was no more earth remaining for the next comer, and soon a nuisance was created. Ultimately the Moule's patent hopper closets had to be removed and they are now to be seen lying disused on the grass in rows like soldiers drilling. A simple metallic pail has been substituted and twice a day a fatigue party goes round and throws lime into all the pails. Once a day these pails are emptied out into larger iron tubs and carted away. This is not satisfactory. The iron tubs have been knocked out of shape and the lids no longer fit properly, so that the lighter particles may be shaken out of them in the course of removal. Proper pails are in use in many parts of the country, particularly for typhoid fever patients, to prevent their contaminating the closets, drains, and sewers. In Manchester, notably, the pail system used to be applied to the greater part of the houses. Over the lid of the pail there should be a bar fitting into a groove and on giving this bar a twist round the edge of the lid would be jammed down on to an indiarubber flange and thus the pail would be rendered air tight. Such pails were in use in Manchester and could be conveyed through the streets without any risk or nuisance whatsoever. Then, again, the pail itself should be removed instead of being emptied on the spot into a larger receptacle. Every time this is done a certain amount of dust must be liberated and blown over the camp. It will be said that this is the fault of the contractor who has undertaken to do the work, but the British taxpayer pays for a sanitary military service which should attend to such matters instead of trusting to some outside contractor. How can a London contractor be expected to know what is necessary for a camp of coloured troops? Some of the military authorities would have preferred trough closets with water constantly running through. As it was necessary to lay a drain through the camp to carry away the slop water such closets might have been connected with this drain. It was, however, perhaps fortunate that this was not done, for the drain was at an early stage blocked and had to be dug up and relaid

The greater part of the coloured contingent sleep in the banqueting hall. They have been amply provided with blankets so as to contend against a coldness of climate to which they are not accustomed. Their beds are certainly too close to each other, but this evil is perhaps sufficiently mitigated by the fact that the hall is some 40 feet high and the louvre windows in the roof are left open at night. Though their health has so far been well maintained.

still there have been some severe colds and there is one case of double pneumonia. Perhaps instruction should be given to the coloured men not to lie about on the grass; for in spite of fitful outbursts of sunshine the earth must retain much of the damp due to the recent heavy rains. Accustomed to hot climates these coloured men are in the habit of lying down on the ground and in the sun whenever they have any leisure. But in a damp, cold country and on a clay soil this practice is accompanied by a certain obvious risk. Notwithstanding, however, the bad weather prevailing during the earlier portion of the visit the coloured contingent seem in any case well satisfied with the attention and the compliments that they have received. It is true that Major E. Atkin, who helped very efficiently to organise their camp, has been a host in himself. His practical knowledge of native life in some of our colonies has stood him in good stead. He has ingratiated himself with the coloured races, knowing how to command and yet how to treat them as fellow-men and brothers. He is ever on the look-out to protect them from the gaping and ignorant rudeness of the Cockney sightseer and seeks to devise contrivances that shall satisfy their wants and harmonise with their customs. If from the political point of view it is important that these coloured fellow subjects should return to their native lands fully satisfied with the attention paid to them in this country, with the comforts they have enjoyed, and with the welcome that they have received, it is also quite clear that any great change in their mode of life and the accompanying dissatisfaction which it might cause would have a depressing effect and would render them all the more likely to contract those diseases incidental to their long journey and the rigour of our northern climate. Therefore it has been necessary to display more than usual organising faculty and forethought so as to prepare a suitable camp where men belonging to a great variety of races could live very much in their own way and yet not transgress any of the essential sanitary laws of this country. That this has been on the whole satisfactorily achieved speaks well for the tact and ingenuity of all concerned.

OBSERVATIONS ON DIET.

By Harry Campbell, M.D., F.R.C.P. Lond,

PHYSICIAN TO THE NORTH-WEST LONDON HOSPITAL; PHYSICIAN TO THE WEST-END HOSPITAL FOR NERVOUS DISEASES, WELBECK-STREET, W.

IV.[1]—Animal *versus* Vegetable Diet.

Animal food is practically confined in this country to eggs, milk (with its derivatives cheese and butter), the flesh of certain mammals (e.g., the ox, sheep, pig, and rabbit), birds and fish (shellfish constitute quite a subsidiary source of food with us). Vegetable foods consist of the cereals (wheat, maize, rice, &c.), the pulses (peas, beans, &c.), the roots and tubers (carrots, potatoes, &c.), green vegetables and fruits (including nuts), and such derivatives of the vegetable kingdom as cane sugar and starch (in the form of sago, tapioca, &c.).

The Composition of Animal and Vegetable Food Compared.

All the nutritive ingredients which go to make up a complete dietary—proteids, fats, saccharides,[2] extractives, and salts—are to be found both in the animal and the vegetable kingdoms; they differ, however, somewhat in the two kingdoms both in their composition and relative proportions, and I shall now consider some of the more important of these differences.

Proteids.—Vegetable proteids contain more carbon and less nitrogen than do animal proteids, and of them "nucleo-proteids," now known to be a source of uric acid, constitute but a small proportion, a fact to be taken account of in connexion with the uric acid diathesis. But while differences undoubtedly exist between the proteids of the two great kingdoms, just as differences exist between the proteids of different foods belonging to the same kingdom (such as those of meat and fish), there is no reason to believe that vegetable proteids are, from the nutritive standpoint, in any way inferior to animal proteids. Nitrogenous equilibrium can be maintained as well on the one as on the other; nor should we expect to find it otherwise, since the vast majority of animals—many, of them endowed with great vitality—are dependent for their proteids upon the vegetable world, while the earliest and most primitive forms of animal life must have derived their proteids from this source alone. Vegetable proteids, at all events when taken in their natural associations, are, however, not so completely absorbed as are animal proteids, and therefore, if all the proteid is to be derived from the vegetable kingdom, need to be taken in larger amount. Thus it has been shown that while only 2 3 per cent. of the proteids in meat escape absorption, no less than 30 per cent. of those in lentils fail to be absorbed.[3] This defective absorption of the vegetable proteids may possibly be due to their large admixture with starch, cellulose, and such-like substances; whether they are more readily absorbed when separated from their natural associations has not, so far as I know, been tested.

Animal and vegetable foods differ greatly in regard to the relative amount of proteid which they contain, the former being much the richer in this ingredient. Thus about one-third of cooked meat and one-third of cheese consist of proteid, the proportion in fish being somewhat less; eggs contain about 13 per cent. On the other hand, vegetable substances, if we except nuts which contain from 15 per cent. to 20 per cent., contain a comparatively small percentage. Bread, e.g., which for a vegetable food is rich in this substance, contains only 6 5 per cent., while green vegetables and fresh fruits are almost devoid of it. The following gives the percentages of proteid in some of the commoner varieties of vegetable foods: Nuts, from 15 to 20; bread, 6·5; boiled rice, 5; dried figs, 5; dried dates, 4 4; cooked haricots, 4·4 (uncooked haricots, 23); peas, 4; prunes and raisins, from 2 to 5; boiled artichoke, 2 3; bananas, from 1 to 5; boiled scarlet runners, 1·7; boiled potatoes, 1; fresh fruits, 0 5; green vegetables, less than 1; cooked beetroot, 0 44; boiled turnips, 0·32; and boiled parsnips, 0·22.

By artificial means both vegetable and animal proteid can be obtained in a concentrated form. Thus aleuronat contains 80 per cent. of the vegetable proteid gluten, and plasmon 70 per cent. of the animal proteid casein.

Fats.—Vegetable fats, in the form of "albene," "nucolene," and olive oil, are as nutritious as butter and other animal fats; but though fat is abundant in such articles as nuts, olives, and oats, vegetable food is, on the whole, comparatively poor in it, many vegetable foods—e.g., rice, potatoes, the pulses, fruit, and green vegetables—being practically devoid of it. We, indeed, depend chiefly upon the animal kingdom for this important constituent of our diet, though one does not see why vegetable fats should not be more employed in the future than they have hitherto been. Various preparations of fats are made from nuts, some of which are said to afford good and cheap substitutes for cooking-butter. When we reflect that sweet almonds contain 54 per cent. of fat, dried walnuts 62 per cent., and dried filberts actually 66 per cent., it is obvious that the vegetable kingdom contains vast stores of fat; and, inasmuch as vegetable fat is cheaper than animal fat and equally nutritious, it is to be hoped that these may be drawn upon in the future more than they have been in the past.

Saccharides.—Under this term I include both starch and sugar. These substances are very sparingly represented in the animal kingdom. Saccharide is present in milk in the form of milk sugar, of which cow's milk contains some 4·5 per cent., and in the flesh of animals, as glycogen, but in quantities so small as to be practically negligible; vegetable foods, on the other hand, are rich in saccharide and constitute the essential source whence we derive it. The following gives the percentages of saccharide in some of the more important vegetable foods: Bread, 51; boiled rice, 41; banana, 22; cooked haricots, 21; boiled potato, 19; nuts, 10; and fresh fruits, from 5 to 10 Such artificial foods as tapioca, sago, arrowroot, cornflower, and mazena may be regarded as saccharide pure and simple.

Extractives.—Extractives are abundant in both animal and vegetable foods, but especially in the former, the extractives and the salts in the lean of meat constituting by weight as much as one quarter that of the proteids present. Fish, on the other hand, is comparatively poor in extractives. Of the exact nature of these substances little is known. We know, however, that animal extractives are largely made up of broken-down proteid—that they are nitrogenous waste products, in fact. Both classes are stimulating alike to gastric digestion and the nervous system generally, but this is especially true of the extractives of meat, which not only constitute the most powerful known excitants to gastric secretion but may so act upon the brain as to cause actual intoxication. The different stimulating power of such foods as butcher's meat, fish, cheese, oats, maize, hay, though partly due to the varying amount of proteid which they contain, is, I believe, chiefly to be explained by reference to the kind and quantity of their extractives, for it varies quite irrespectively of the amount of proteid present in them Fish and cheese, which are poor in extractives, are much less stimulating than is meat; oats have, as is well known a peculiarly stimulating effect on horses.

---

[1] Nos. I., II., and III. were published in The Lancet of May 24th (p. 1486) and 31st (p. 1554), and June 14th (p. 1712), 1902, respectively.

[2] I use the term "saccharide" synonymously with "carbohydrate."

[3] Robert Hutchison: Food and Dietetics, p. 164.

Salts.—Vegetable foods contain more alkali than do animal foods and are especially rich in potassium; animal foods, on the other hand, contain more sodium and lime. It is especially in green vegetables, potatoes, and fruit that potassium is found; it is less abundant in the cereals and the pulses, both of which are, however, rich in lime. Vegetable foods are abundantly supplied with vegetable acids, all of which are oxidised in the body into carbonates, and these, uniting with an alkaline base, pass out by the kidneys, thus rendering the urine alkaline. This is the effect of most vegetable foods, animal food, on the contrary, tending to increase the acidity of this excretion. The cereals and pulses, owing to their deficiency in vegetable acids and their richness in lime, tend to act like animal food in this respect and to increase acidity. Acids develop in meat on hanging and are abundant in the flesh of hunted animals. These acids, like the extractives of meat, stimulate gastric digestion.

Not only do vegetable foods differ from animal foods in regard to the nature and proportion of their nutritive constituents but also in being more bulky. This bulkiness of vegetable food is partly due to its waterness, which is still further increased by cooking; partly to the fact that saccharide, of which vegetable food is chiefly composed, is two or three times more bulky than its dynamical equivalent of proteid or fat; and partly to the presence of undigestible cellulose. This substance is itself a saccharide and, unlike the herbivora which are provided with special means for converting it into soluble saccharide, man has no power of digesting it, such disintegration as it suffers in his alimentary tract being brought about by bacterial action with the formation of simple chemical substances having no nutrient value.[2] Some vegetables, such as cabbage, consist of little more than cellulose, water, and salts, and are practically valueless as sources of energy. Now the vast stores of starch contained in the vegetable kingdom are all imprisoned in cellulose compartments, and for this reason the starch in raw vegetable food, unless this is subjected to prolonged mastication, so as to break up the cellulose framework, is of little nutritive value to man. Judge, then, how greatly he increased his supply of nutriment by the discovery of cooking, for by its means the starch granules are made to swell up and burst their cellulose prisons, the starch thus liberated being freely digestible by man.

The Effect of Animal and Vegetable Foods Broadly Contrasted

Though "animal food" includes fish, fowl, eggs, and milk, as well as butcher's meat, many when told not to eat too much of it think it sufficient merely to curtail their allowance of "meat," an entirely inadequate measure and founded on an erroneous idea of what animal food includes, seeing that an excess of fish, or fowl, may be quite as injurious as an excess of meat. In what follows "animal food" must be taken to include fish, flesh, and fowl, but especially the latter two, milk and eggs being left out of consideration. On the other hand, vegetable food must be taken to mean the ordinary vegetable produce consumed by the strict vegetarian, and not this diet fortified by vegetable proteid artificially isolated.

Vegetable food by reason of its bulkiness is apt to distend and permanently to dilate and lengthen the alimentary canal; it also puts more work upon the digestive organs than does animal food, and diverts a corresponding amount of blood and energy from other parts whose efficiency is to this extent impaired. This is one reason why the vegetarian is apt to show less energy than the animal feeder or the mixed feeder. The bulkiness of a purely vegetarian diet, its comparative non absorbability, and the presence in it of the highly fermentable ingredients have the further effect of stimulating peristalsis and of causing the fæces to be far more abundant than is the case with a purely animal diet. Vegetable food is more liable to ferment and produce flatulence than is animal food, an additional reason why it should cause distension of the primæ viæ; on the other hand, vegetable food, unlike animal food, is incapable of undergoing putrefaction. Animal food, while putting less mechanical work upon the stomach than vegetable food, is at the same time far more stimulating to the gastric glands, owing to its richness in proteids, acid salts, and energising extractives, and it is largely owing to this local effect on the stomach that it is more satisfying and stimulating than vegetable food.

We have thus far dealt with the local effects on the alimentary canal of the two classes of diet, let us now compare their effects after absorption.

Animal food, containing as it does more proteid than does vegetable food, is more stimulating to metabolism, for not only are proteids rapidly katabolised, but they cause a sympathetic augmentation in the katabolism of saccharides and fats.[3] It is for this reason that an animal diet makes for leanness; vegetable food, on the other hand, owing to its richness in saccharides favours the deposit of fat and, unlike animal food, causes a wateriness of the tissues, so that while animal feeders tend to be lean and hard, vegetable feeders are apt to be fat and flabby Animal food, possibly owing to the large amount of urea to which it gives rise, causes an abundant flow of urine; vegetable diet has the opposite effect, and this probably explains why the tissues are drier on the former than on the latter diet, animal food promotes the acidity of the urine, while most vegetable foods tend to render this fluid alkaline, the exceptions being the cereals and pulses which have rather the opposite effect.

The nervous system appears to need for its highest manifestations a rich supply of proteid, this withheld, "nervous energy" or "go" flags. After a meal of meat an individual is more lively than after one of vegetable food in which there is a dearth of proteid, the stimulating effect of the proteids of the meat being further enhanced by the similar effect on gastric digestion and on the system generally of the extractives in which meat abounds, I would suggest that the waste products of proteid katabolism have also a stimulating action Vegetable food, on the other hand, is not only apt to be deficient in proteid but contains comparatively few stimulating extractives; the large demands its bulk makes upon the digestive organs tend, moreover, to induce lethargy.

Hutchison[4] lays stress upon the difference in energy shown by the animal and vegetable feeder, comparing the restless tiger, ever ready to pounce upon its prey, with the placid ruminant dreamily chewing the cud Nevertheless, the purely vegetable feeding animal is by no means always lacking in nervous energy Witness the fierce energy displayed by the wild boar and the gamecock even though confined to a strictly vegetable diet, again, what animal shows more "nervous energy" than a thorough-bred, which, moreover, is probably capable of greater endurance than any of the carnivora. In fact, the herbivora are, on the whole, far more enduring than the carnivora by reason of the large amount of food they consume in the form of saccharide. Nor must the energetic nature of the carnivora be attributed solely to their diet; living, as they do, on other animals they are compelled to hunt and fight and kill, and thus by the survival of the fittest the fiercest and most aggressive tend to survive. I do not, of course, contend that a diet of flesh, especially butcher's-meat and bird, does not tend to excite the nervous system, there can be no doubt that it does; dogs fed on meat only are fiercer than are those which are mixed feeders. In irritable states of the nervous system much good may often be done by de-animalising the diet, and it is certain that flesh eating communities display more energy than do those which are wholly, or almost wholly, vegetarian. I merely wish to emphasise the fact that a high degree of energy is not the exclusive prerogative of the flesh eater

The Comparative Suitability of Animal and Vegetable Diet

How far is man adaptable to an animal, a vegetable, or a mixed diet? It is needful for the physician to study the question in all its bearings. Some have argued that man is by nature essentially a vegetable feeder on the ground that he is descended from an ape-like creature and that all apes are vegetable feeders. But, as a matter of fact, the anthropoid apes, man's nearest relatives, are by no means wholly vegetarian; they devour many kinds of animals and subsist largely on birds and bird's eggs. Moreover, the digestive system of man, including his teeth, to say nothing of his instinct to kill, proclaims him to be largely carnivorous; and, in fact, all the evidence goes to show that he is naturally more of a carnivorous than a vegetable feeder. As one writer puts it: "Man is carnivorous. It is his misfortune, but it is so." One would willingly think otherwise, for who can contemplate with equanimity the wholesale slaughter of animals, with all its gruesome accompaniments, in order that we may feed on their flesh? But facts have to be recognised.

---

[2] The latest investigations tend to show that man is incapable of deriving any nutriment from cellulose.

[3] Physiologists do not appear to offer any explanation of this.

[4] Op cit., p. [illegible]

But while man is carnivorous he is also herbivorous—i.e., he is by nature omnivorous, a mixed feeder. Some races subsist solely on animal, others solely on vegetable, food, but taking the whole world over it is found that man thrives best on a mixed diet—i.e., experience, which is in the last resort the only reliable test, confirms the conclusion derived from ancestral and anatomical considerations, and the accumulated experience of many countries through many ages goes to show that man thrives best on a dietary in which proteids, fats, and saccharides bear a certain proportion to one another. Now this proportion cannot be obtained on a purely animal diet or on a purely vegetable one unless fortified in a manner to be referred to presently. In the former case a quantity of proteid greatly in excess of his requirements has to be consumed in order to secure the necessary quantity of carbon, and in the latter the needful quantity of nitrogen can only be obtained by consuming an excess of saccharides and cumbering the alimentary tract with a large mass of food, which is objectionable not only for mere mechanical reasons but on account of the enormous demands it makes upon the digestive system, to which it diverts a large amount of blood and energy which might be employed elsewhere. These difficulties are got rid of by combining animal and vegetable food so as to secure a proper proportion of the various nutritive ingredients, that proportion being obtained by taking about one of the former to two of the latter. If the diet be either too much animal or too much vegetable certain evils result. These we will now consider.

Evils resulting from a too highly Animal Diet.

In the following remarks I shall exclude from consideration milk, butter, cheese, and eggs, all of which, however, strictly speaking, come under the category of animal food.

The evils resulting from a dietary containing an excess of fish are not so pronounced as are those resulting from one comprising too much "meat" or bird, and in practice we are much more concerned to keep down the consumption of these than of fish. This suggests that it is not so much an excess of proteid which is injurious as of the associated extractives, a conclusion which is supported by the fact that the troubles which result from an excess of bird are not quite the same as those resulting from an excess of meat. Nevertheless, there can be no doubt that an excess of the proteids themselves, especially, perhaps, of the nucleo-proteids, causes injury by casting an abundance of nitrogenous waste products upon the circulation.

The effect of a highly animal diet depends among other things upon idiosyncrasy, age, and habit of life. Some are by nature so constituted that they can consume an abundance of animal food—meat, for instance—without apparent harm, while others become gouty and "rheumatic" on a comparatively small quantity of it. Age has a decided influence. Thus a superabundance of meat is perhaps apt to disagree during the early years of life; during the subsequent years of growth and development a highly animalised diet is better borne than at any other period; after middle life the evils resulting from consuming an excess of animal food, especially meat, increase year by year and it is certain that the aged should partake of it very sparingly. Nothing, indeed, better attests the evil effect of an excessive meat diet than its influence upon length of life. Butchers are as a class short-lived, and Humphry has shown that the majority of centenarians are moderate meat-eaters.

But the effect of a highly animalised diet depends more than anything else upon whether a sedentary or an active life is being led; the more active the life the larger is the amount of animal food that can be taken with impunity, an active life promoting oxidation and the elimination of waste products. It should be remembered that all the purely carnivorous animals are necessarily highly active, since they have to hunt for their prey, and it is a noteworthy fact that such races among men as are purely carnivorous lead highly active lives. Thus the Pampas Indians, who subsist for months together entirely on flesh, spend most of their time in the saddle, and it is only under conditions of this kind that a purely animal diet can be tolerated. Those leading inactive lives are necessarily injured by such a diet, a statement which is true of carnivorous animals as well as of men; it is well known that a dog that is kept about the house and not allowed plenty of exercise gets ill if its diet is restricted to meat.

The moral of all this is that the inactive should not allow the proportion of animal food which they consume to be too high; though curiously enough they are less able to tolerate a purely (unfortified) vegetable diet than are those leading active and laborious lives, it being more difficult for them to burn off the large amount of saccharide which such a diet must necessarily contain if they are to secure the proper proportion of proteids. It is true that a person may for a time thrive on a purely meat diet even while resting in bed, especially if a large quantity of water be taken with it so as to aid the elimination of the extractives and waste products; the digestive system, relieved of the necessity of coping with the starchy and other ingredients which a mixed diet entails, may be benefited by this plan of treatment. But such a diet can rarely be continued beyond a few weeks without doing injury unless a highly active life be led.

In this country most people except the poor tend to eat too much animal food.

The Evils of a Diet which is too purely Vegetable.

While it is certain that health can be maintained on a purely vegetable diet it is very doubtful whether such a diet unless selected upon a special plan will allow of the attainment of the fullest vigour of mind and body. Unless most carefully chosen it is apt to be unduly bulky and so to make an undue demand on the digestive powers, thereby diverting to them too large a proportion of the total energy of the organism. When we add to this the facts that a vegetable diet is apt to be deficient in proteid and that stimulating extractives are poorly represented in it, it is not surprising that the pure vegetarian is apt to lack energy; he is, moreover, prone to obesity and apt to offer a low resistance to disease.

Vegetable food has, further, a tendency to ferment and thus to add to the distension caused by mere bulk. This is especially the case with the potato, green vegetables, and pulses; the large starch granules of the potato appear to be very susceptible of fermentation, while the sulphur which is abundant in the pulses, especially beans, predisposes to the formation of SH_2; peas contain less sulphur and are less apt to cause flatulence, and lentils still less so. In regard to green vegetables it should be remembered that the fresher they are the less are they liable to ferment; hence the great importance of eating them fresh; unfortunately the early stages of decomposition are not so evident in the case of vegetable as of animal matter. Some have contended that the pulses, containing as they do a large quantity of lime, predispose to atheroma and that communities that subsist largely on them are especially prone to this disease, but the evidence in favour of this statement is slender.

Inasmuch as the cereals and the pulses, unlike other vegetable foods, tend to increase urinary acidity and to conduce to general acidity they may favour gout and "rheumatism." Haig traces the rheumatism met with among the natives of India to the fact that they live largely on these articles of diet. Acid fruits, such as strawberries, may set up joint-pains in the rheumatic and gouty, but all vegetable acids are oxidised in their course through the body into carbonates, which after uniting with potassium and sodium are secreted by the kidneys, thus tending to diminish the acidity of the urine. Again, sugar is in some prone to undergo acid fermentation in the stomach and, like acid fruits, is by some physicians proscribed in rheumatism and gout, but the acidity produced by acid fruits and sugar is less apt to arise on a purely vegetable than on a mixed diet, and it is chiefly, therefore, as part of this latter diet that we need to proscribe them.

followed by jaundice. The biliary fistula which followed was subsequently cured by the removal of another gall-stone from the common duct by choledochotomy. The patient is now well

CASE 59.—The patient, a woman, aged 38 years, was seen by me at the General Infirmary. There had been colic and jaundice for six months with loss of weight and of strength. Deep jaundice was present. There were gall-stones in the common duct. Duodeno-choledochotomy performed on Jan. 31st, 1901, resulted in a good recovery and the patient was well some months later.

CASE 60.—The patient was a woman, aged 49 years She was seen by me at the General Infirmary. For six years colic had persisted with varying jaundice. There were eight large stones and some small ones in the common duct. On March 22nd, 1901, duodeno-choledochotomy was performed, a good recovery ensuing, and the patient was well some months later.

P.S. (March 21st, 1902) —Since handing in my paper to the secretary of the society I have had eight additional cases of choledochotomy, all of which have recovered. It may interest the Fellows of the society to note that the final paragraph of the paper was a forecast; fortunately, the unavoidable postponement of the communication has enabled me to prove that a 5 per cent. mortality was a reasonable estimate, for it will be seen that of the cases—21 in number—operated on since July of last year all have recovered; and that including all my cases of choledochotomy since June, 1900, there has only been a mortality of 5 5 per cent.

Leeds

ON A CASE OF PNEUMOCOCCIC GASTRITIS AND GENERAL INFECTION,

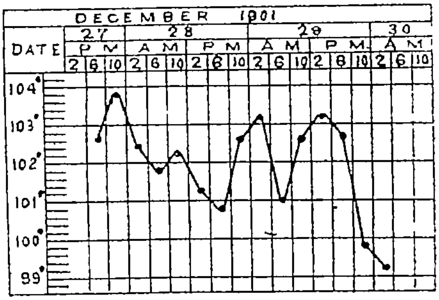
WITH SOME REMARKS ON THE INFECTION OF MUCOUS MEMBRANES BY DIPLOCOCCUS PNEUMONIÆ.[1]

BY ALEXANDER G. R FOULERTON, F R.C.S. ENG ,
LECTURER ON BACTERIOLOGY TO THE MIDDLESEX HOSPITAL.

WHEN dealing lately with the pathology of pneumococcic infection as a whole[2] it was not possible for want of time to refer otherwise than briefly to the lesions of mucous membranes which may be caused by diplococcus pneumoniæ. Such lesions have attracted *comparatively little* attention from pathologists, partly because their importance has been overshadowed to some extent by other more conspicuous results of pneumococcic infection—such as pneumonia, peritonitis, meningitis, and arthritis—and partly because of some technical difficulty in the isolation of this particular organism when it occurs in lesions of *mucous surfaces which will frequently* be so contaminated with other bacteria that the primary causative agent may be difficult of identification. A considerable number of writers have, however, referred more or less casually to various morbid conditions of mucous membranes, such as laryngitis and enteritis, occurring in fatal cases of pneumonia; and it is probable that pneumococcic lesions of mucous membranes are of much more frequent occurrence than the number of recorded cases in which a satisfactory bacteriological examination has been made would indicate.

The case of acute membranous gastritis due to pneumococcic infection which will be next referred to is of interest as being, so far as I can ascertain, the first case of the sort recorded.

The patient, aged 26 years, was admitted into Dr. W Pasteur's wards at the Middlesex Hospital under the care of Dr. F. J. Wethered, and I have to thank both these gentlemen for their permission to make use of the clinical notes of the case. The patient was admitted on Dec. 27th and the following history was obtained. A fortnight previously he came under treatment for a "quinsy" and had remained ill ever since. Three days before admission a free attack of epistaxis came on whilst he was blowing his nose and since then there had been an almost continuous oozing of blood from the nostrils. On the day before his admission he had brought up by the mouth a quantity of dark-coloured matter which had a very disagreeable smell. On admission the patient was anæmic to an extreme degree. His lips were swollen and in the skin of the back, around the lips, and on the cheeks there were a number of petechial hæmorrhages. There was coagulated blood in the nostrils, on the lips, and on the gums round the teeth. The breath was very offensive and the tongue was dry and covered by a dark grey fur. The pulse was frequent, small, and soft. On the 28th the oozing of blood from the nostrils continued and no further change of any importance in the symptoms was noted On the 29th the patient was restless, the respiration-rate was hurried, and the pulse was frequent, very small, and of low tension. The temperature began to fall towards the evening and the patient died early the next morning with signs of urgent dyspnœa. It must be noted that throughout the illness there had been no indications in the way of local pain or vomiting which would have suggested any gastric disturbance.



The examination of the body was made about seven hours after death on a cold day Rigor mortis was present and the body appeared to be well-nourished generally. The skin had a blanched appearance and there were numerous petechial hæmorrhages scattered over its surface; there were several "mulberry spots" on the chin and on the cheeks. There was a deepish, ragged ulcer in the right tonsil and a large blood-clot occupied the upper part of the pharynx. The œsophagus was of natural appearance. The stomach was of normal size and contained some dark-coloured fluid matter which had an extremely offensive "cheesy" smell The viscus was lined from end to end with a roughish exudation membrane which towards the cardiac extremity was of an almost black colour and was intimately *attached to the underlying mucous membrane, and towards* the pylorus was of a greyish colour and less closely attached, so that here it could be peeled off in small flakes from the mucous membrane underneath in which there were numerous petechial hæmorrhages. The rugæ of the stomach were swollen and stood out prominently. The wall of the stomach as a whole was slightly thickened but the increase appeared to be due mainly to the new membranous formation. The exudation membrane terminated abruptly at the cardiac and pyloric openings The general appearance of the stomach was striking and bore some superficial resemblance to what is seen in a severe case of poisoning by a mineral acid. The serous coat of the stomach was somewhat congested, and the peritoneal sac contained a few ounces of slightly turbid fluid. There were small, petechial hæmorrhages on the pulmonary pleuræ, on the epicardium, and on the surface of the liver and kidneys. There was an interstitial hæmorrhage, of an area of about the size of a shilling-piece close to the surface of the right lung and there was a small excess of blood-stained fluid in the pericardial sac. Beyond these lesions nothing of importance was noted at the examination.

Bacteriological examination.—Various culture tubes were inoculated (1) from the spleen juice, (2) from the blood of the femoral vein, (3) from the substance of the exudation membrane on the surface of the stomach, (4) from the juice of the hæmorrhagic area in the right lung, and (5) from the juice of one of the "mulberry spots" on the face. From the blood of the femoral vein, from the mulberry spot, and from the hæmorrhagic area in the lung pure cultures of diplococcus pneumoniæ were obtained. From the tubes inoculated from the exudation membrane from the stomach two species of bacteria were isolated—diplococcus pneumoniæ and a

Vegetable Diet fortified by Vegetable Proteid.

When we reflect that the vegetable kingdom contains all the individual food-ingredients needful for life, and that the inferiority of a purely vegetable dietary is essentially due to its bulkiness and lack of proteids, the question naturally occurs whether it would not be possible to isolate a pure vegetable proteid (just as we separate casein from milk) and by adding it to vegetable food—e.g., wheaten flour—secure a food which should contain proteid in the needful proportion and at the same time not be too bulky. This would dispense with the necessity of overloading the system with saccharide. Such a substance has been prepared from the gluten of wheat, and is known as "aleuronat," and by fortifying wheaten flour with it a bread can be obtained which, with the addition in proper proportion of vegetable fat, constitutes a diet in which all the foodstuffs are presented in the needful proportions. This is the direction in which the consistent vegetarian must look, and I personally can see no reason why his dream should not be realised. Another way of obtaining the necessary proteid in a compact form is by means of preparations obtained from nuts. Thus Fromm's Extract, obtained by crushing nuts and removing the excess of cellulose and oil, contains 22 per cent. of proteid, 31 6 per cent. of fat, 8 per cent. of saccharide, and 12 8 per cent. of mineral matter.[7] I do not see why food of this description should not have a great future before it.

There are those who make light of vegetarianism and regard its votaries as mere cranks, they point scoffingly to the great difference between the stomach of the ox and of man, and say that it is absurd to suppose that man, like that animal, can subsist on a vegetable diet; but no reasonable person has ever contended that man can subsist on the diet of the ox; this is manifestly impossible since he is, as we have seen, incapable of digesting cellulose. They conveniently ignore the fact that the vegetable food which man consumes is totally unlike that which forms the food of the ruminant: in the first place, man has by cultivation profoundly modified vegetable food, such as wheat, rice, beans, the potato, the date, and the fig, for his own use, and thus has obtained the food ingredients in a concentrative form; and this concentration he has carried a step farther by milling, grinding, and other means whereby the indigestible portions are separated from the digestible. Nay, more than this, he has actually wrested from the vegetable kingdom the various nutritive ingredients—starch, sugar, fat and proteid, in their pure, or almost pure, form; and when to these facts is added the further one that he has been able greatly to increase the digestibility of vegetable substances by cooking and artificial digestion the speciousness of the comparison between man and the ruminant becomes apparent. Even the carnivorous dog, which is totally incapable of subsisting on the food of the horse or the ox, can freely digest sugar, starch, and other food ingredients which man has cunningly extracted from the vegetable world.

Vegetable Diet fortified by Eggs and Milk.

Hitherto the so-called vegetarian has obtained the needful supply of proteid from milk and eggs; cheese contains, weight for weight, more proteid than meat; from the casein, moreover, plasmon and protene, now largely used in the sick room, are prepared; the latter is sold as protene flour from which protene bread is made, a food which with the proper proportion of butter, another derivative of milk may to made to contain the three great food-stuffs, proteids, fats, and saccharides, in the proportions needful for health. Fat being a highly concentrated form of food, and the vegetable world yielding few fats, such as olive-oil, which can be taken with relish in any quantity, the butter, like the cheese obtained from milk, enables the bulk of vegetable food greatly to be reduced.

Milk and eggs, however, are animal foods and the same sentimental objection which attaches to the eating of flesh attaches to their consumption also. I am not going to advance in support of this statement the spurious argument put forward by some to the effect that those who object to kill in order to obtain food should not, to be consistent, eat eggs, on the ground that they are really alive and are capable of developing into individuals. The subject should not be approached in any narrow, carping spirit, but seriously, reverently. The vegetarian is against killing something which has *lived and felt*. The argument I am going to use is a much more weighty one—i e., that the consumption of milk and eggs necessitates a wholesale killing, for in order that a farmer may get a profit on his eggs and milk, he has to kill off a large number of cocks which yield no eggs and bulls which give no milk. If he reared them all and allowed them to die a natural death, not only would his farmyard be a perfect pandemonium, but his expenses would be such that in order to sell his eggs and milk at a profit he would need to demand a prohibitive price. It follows that those who consume these articles, though they do not eat flesh, are yet accessory to the slaughter of animals.

UNIVERSITY OF OXFORD: DECREE AND REGULATIONS FOR THE READERSHIP IN OPHTHALMOLOGY.

IN a Convocation holden on Tuesday, June 17th, 1902, the following decree and egulations were approved:—

DECREE AS TO READERSHIP IN OPHTHALMOLOGY.

Whereas Margaret Ogilvie, widow, has offered to the University a capital sum which will provide not less than £200 a year for the endowment of a university reader in ophthalmology;

And whereas it is the intention of the said Margaret Ogilvie, primarily to encourage the prosecution of original research in ophthalmology, and, secondarily, to provide instruction—by means of lectures (clinical and systematic) and demonstrations—in diseases and defects of the eyes and their treatment, for members of the University and for legally qualified members of the medical profession;

The University accepts the offer, approves of the regulations made in that behalf, and hereby records its gratitude for Mrs. Ogilvie's munificence.

REGULATIONS FOR THE READERSHIP IN OPHTHALMOLOGY.

1. The annual income of the readership endowment shall be applied in and for the encouragement of original research in ophthalmology and also for providing at the Oxford Eye Hospital ordinarily, and elsewhere in Oxford when expedient, instruction in the nature and treatment of eye diseases and defects for members of the University and for members of the medical profession

2. If and so long as the Hebdomadal Council shall be allowed to nominate three members of the board constituted for electing the senior honorary surgeon to the Oxford Eye Hospital, the said surgeon shall be appointed and designated the Margaret Ogilvie's Reader in Ophthalmology. Three-fourths of the net annual income from the endowment shall be paid to the reader; and one-fourth shall to applied under his direction in providing such assistance in the pathological department of the hospital and such apparatus and museum requisites as he may consider necessary.

3. The electoral board hereinbefore referred to shall consist of—(*a*) The vice-chancellor; (*b*) the chairman and the vice-chairman of the Oxford Eye Hospital; (*c*) the treasurer of the Radcliffe Infirmary; (*d*) the regius professor of medicine in the *University of Oxford*; (*e*) the President of the Royal College of Surgeons; (*f*, *g*, *h*) three members nominated by the Hebdomadal Council on each occasion.

4. The lectures to be delivered by the reader shall not be less than 12 during the University academical year; that is to say, *four in each* term (Easter and *Trinity terms* being counted as one); at least six of the lectures shall be systematic and the remainder may be clinical.

5. If during any year that shall expire on the first day of September the reader shall have failed to reside 30 weeks *within one mile* and a half of Carfax, he shall cease to hold his readership, but shall not on that ground be incapable of re-election

6. If the reader ceases to hold the appointment of honorary surgeon to the Oxford Eye Hospital he shall thereupon cease to hold the readership

7. A reader who has reached the age of 60 years shall cease to hold *the readership*. But the electoral board shall have power to re-elect him, if they think fit for a further period not exceeding five years

8. If the senior honorary surgeon to the Oxford Eye Hospital ceases to hold the readership, no election of a reader shall be held so long as he shall be surgeon, and the income arising from the trust fund during the vacancy of the readership shall be invested in augmentation of the capital of the trust.

9. The amount which may accrue from the accumulation of income during any abeyance of the readership shall be invested, and the annual *income thereof* shall be applied to the furnishing of apparatus and diagrams and other requisites for research in ophthalmology and for purposes of instruction.

10. The reader shall be entitled to require from medical students a fee not exceeding two pounds for any University term, but no fee shall be payable by any registered member of the medical profession.

11. The reader shall submit annually at the commencement of the University academical year to the board of the Faculty of Medicine a *brief report detailing* the original research conducted by him during the 12 months immediately preceding.

12. The reader shall be subject to the jurisdiction of the visitatorial board

13. Robert Walter Doyne of Keble College, F.R.C.S., honorary surgeon to the Oxford Eye Hospital and honorary consulting ophthalmic surgeon to the *Radcliffe Infirmary*, shall during his tenure of the first-named appointment be constituted the first Margaret Ogilvie's reader in ophthalmology.

14 The collection of preparations and drawings illustrating the pathology of the eye, presented by Mr. Doyne as a further endowment of the readership shall, together with any future additions thereto, be under the charge of the reader. This collection, together with all collections, preparations, drawings, and apparatus purchased out of the

income of the Ogilvie Trust Fund, shall be the property of the University. The expenses connected with the maintenance thereof shall be defrayed out of the income of the trust fund.

15. The trust fund shall be transferred to the curators of the University chest and the capital thereof invested by them in the name of the chancellor, masters, and scholars of the University.

16. These regulations shall be subject to alteration by Convocation at any time with the consent of the donor during her lifetime; provided that the main object of the foundress as set forth in the decree be always had regard to.

CHARING CROSS HOSPITAL: MASONIC CEREMONIAL.

ON Friday, June 20th, the foundation-stone of the addition to Charing Cross Hospital was laid by H.R.H. the Duke of Connaught, K.G., Most Worshipful Grand Master of the United Grand Lodge of England, with full Masonic ceremony in the presence of H.R.H. Princess Louise, Duchess of Argyll, President of the hospital, and a large and distinguished company of guests.

On arrival His Royal Highness was received by the President of the hospital and a deputation of grand officers. A deputation of the Council of the hospital was then presented to His Royal Highness. After the presentation the Grand Master and the grand officers in attendance, wearing their Masonic clothing, entered the pavilion in procession in the following order: the Deputy Grand Director of Ceremonies (Mr. E. Armitage), three Masters of Lodges (including Dr. John Abercrombie, Master of the Chère Reine Lodge) bearing the cornucopia and ewers with wine and oil, two Grand Deacons (Mr. Thomas Wakley, jun., and Mr. Henry Grey), the Grand Superintendent of Works (Mr. H. L. Florence) with the mallet, the President of the Board of Benevolence (Mr. J. H. Matthews), the Grand Secretary (Mr. E. Letchworth) with the plate, the President of the Board of General Purposes (Mr. R. Loveland Loveland, K.C.), the Grand Registrar (Mr. J. Strachan, K.C.) bearing the great seal, the Grand Treasurer (Captain J. Barlow) bearing a phial containing the coin to be deposited in the stone, the Junior Grand Warden (Major-General the Hon. H. F. Eaton, C.B.) with the plumb rule, the Senior Grand Warden (the Earl of Donoughmore) with the level, the Grand Chaplain (Canon Quennell) bearing the Sacred Law on a cushion, the Deputy Grand Master (the Earl of Warwick) with the square, the Grand Sword Bearer (Major-General Astley Terry), the Most Worshipful the Grand Master H.R.H. the Duke of Connaught, K.G., and two Senior Grand Deacons (Mr. C. N. P. Phipps and Dr. A. E. Sansom). Her Royal Highness the Princess Louise, Duchess of Argyll, President of the hospital, then addressed the Grand Master and requested His Royal Highness to lay the foundation-stone according to Masonic form. The Grand Master said he would be happy to comply with Her Royal Highness's request; the vessels of corn, wine, and oil were deposited on a pedestal placed for their reception, and the upper stone having been raised and the lower one adjusted the Grand Master addressed the assembly, after which the Grand Chaplain offered a prayer. The Grand Secretary next read the inscription on the plate and the Grand Treasurer deposited the phial containing the coins. The cement was spread on the upper face of the lower stone and the M.W. the Grand Master adjusted the same with a trowel handed to him for the purpose, after which the upper stone was slowly lowered with three distinct stops. The Grand Master then proved the just position and form of the stone by the plumb rule, level, and square, which were successively delivered to him by the Junior Grand Warden, the Senior Grand Warden, and the Deputy Grand Master. Being satisfied in these particulars His Royal Highness gave the stone three knocks with the mallet which was handed to him, saying: "I find this stone to be plumb, level, and square, and I declare it to be duly prepared and truly laid and that the craftsmen have worked well." The cornucopia containing the corn and the ewers with the wine and the oil were next handed to him and the Grand Master strewed the corn and poured the wine and the oil over the stone with the accustomed ceremonies. The architect was presented to the Grand Master and delivered to His Royal Highness the plan of the intended building. The Grand Master having inspected the plan returned the same to the architect, together with the several tools used in proving the position of the stone, and desired him to proceed to the completion of the work in conformity with the plan, after which the Grand Chaplain pronounced a blessing.

Mr. DRUMMOND, the treasurer of the hospital, in moving a vote of thanks to His Royal Highness, referred to the facts that some 70 years ago the foundation-stone of the old building was laid with a similar ceremony by the late Duke of Sussex, that the late beloved Queen Victoria throughout her long life had shown a deep interest in the hospital (in fact, they possessed the first Victoria Ward of any hospital), and that for about 20 years the late Duke of Edinburgh had been their President, and by his efforts in promoting the success of the bazaar at the Albert Hall had enabled the committee to commence the new building. They required £80,000 to complete the work. As treasurer he was bound to make the customary appeal, but the public having been so generous to them in the past he and the rest of the committee looked forward to the future with the greatest confidence. In commemoration of that day they asked His Royal Highness graciously to be pleased to name one of the new wards.

Sir JOSEPH FAYRER, in seconding the motion on behalf of the medical staff, referred to the vast benefits that were conferred by hospitals on every member of the community, from His Majesty the King on the throne down to his meanest subject, and touched on the special service rendered by Charing Cross Hospital.

The DUKE OF CONNAUGHT, who was received with enthusiasm, said that he was indeed very sensible of the kind words which had fallen from Mr. Drummond and Sir Joseph Fayrer and that it required no vote of thanks for him to assure them of the very great pleasure with which he attended that day in compliance with the wishes of his beloved sister, their President, to lay the foundation-stone of the new buildings with full Masonic honours. Speaking in the name of the Grand Lodge and of all Masons—a large and influential body of His Majesty's subjects—he assured them that they very much appreciated the opportunity of performing the ceremony and of, if possible, raising their opinion of Freemasons and enabling them to see what a loyal body of men English Freemasons were. He trusted that the ceremony had interested those who perhaps for the first time had witnessed it. He alluded to the close connexion which members of his family had had with Charing Cross Hospital and hoped and believed that now, under the presidency of his sister, Princess Louise, it would flourish in the manner they would all wish it to do. Their beloved Sovereign the King had for many years taken a deep interest in everything connected with the hospitals of this metropolis and had made every endeavour to promote and to increase the funds necessary for the working of these most important but very expensive institutions. His Royal Highness concluded by saying that he hoped that the new extension, the foundation-stone of which he had that day had the great pleasure of laying, when completed would make Charing Cross Hospital one of the finest and most complete of the splendid hospitals of which they were all so proud in this great city. He thanked them for their kind vote of thanks.

The M.W. Grand Master then said that he should like to name the new ward the "Alfred Ward" in memory of his dear brother, but on being subsequently informed that there was already an Alfred Ward in the hospital he rose again and said that in that case, although it had been suggested that it might be called the "Duke of Edinburgh Ward," he thought that everyone present would agree that there could be no more appropriate name than the "Louise Ward"—a pronouncement which was received with much applause.

It may be interesting to record that the mallet used by His Royal Highness in the ceremony was the one used by Charles II. in laying the foundation-stone of St. Paul's Cathedral. It was subsequently presented by Sir Christopher Wren to the Lodge of Antiquity, of which he was Worshipful Master. On the present occasion it was specially lent by the Lodge of Antiquity for use by the M.W. Grand Master. Before and after the ceremony the band of the Royal Marine Light Infantry supplied a pleasing programme of music.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. von Boehm, formerly Director of the General Hospital, Vienna, at the age of 75 years.—Dr. Polaillon, the well-known surgeon of the Hôtel Dieu in Paris, at the age of 66 years.—Dr. Ferdinand Sommer, formerly Professor of Anatomy in the University of Greifswald. His published papers dealt mainly with zoological matters and the anatomy of the lower animals.

Looking Back.

FROM

THE LANCET, *SATURDAY, JUNE 26*, 1824.

ARTIFICIAL CASTOR OIL.

One drop of the oil of Croton, mixed with an ounce of the Oleum Papaveris forms a preparation very nearly resembling castor oil, and a table-spoonful of one will produce the same effects as a *table-spoonful of* the other The mixture has been used with great success in our hospitals, and, as castor oil is so dear, we strongly recommend the general adoption of this substitute.—*Hufeland's Journal der Practischen Heilkunde*

Vaccination.—On the 14th ult. the physicians of Berlin celebrated, as they have done for these fourteen years past, Dr Jenner's grand discovery of vaccination. From the lists sent to the Society from all parts of the kingdom, it appears that the number *of* individuals vaccinated last year was 330 905.—The number would probably have been 360,000 if the lists had been complete

The newly invented apparatus kept at the infirmary for extracting poisons from the stomach, was used for the first time in this town on Friday last. Laudanum had been taken, for the purpose of self destruction , the usual emetics had been administered without any effect, as is frequently the case under similar circumstances in consequence *of the* insensibility produced by the poison. The laudanum was extracted, by first forcing a quantity of warm water into the stomach, and then immediately withdrawing the whole contents by means of the new instrument.—*Derby Reporter*

At a meeting of the Philosophical Society, on Monday se'nnight, a paper was read by the President, Dr HAVILAND, on the cases of secondary small-pox, and of small pox after vaccination, which had occurred amongst members of the University of Cambridge during the last year, out of twenty seven cases, five only were severe, and three of those, which were cases of secondary small pox were much more so than the *two others*, which occurred *after vaccination.*—*Norwich Mercury*

LORD NORBURY'S NEWEST.—His Lordship while lately indisposed, was threatened with a determination of blood in the head. Surgeon C—l accordingly opened the temporal artery; and whilst attending to the operation, his Lordship said to him, in his usual quick manner, "C—l, I believe, you were never called to the Bar?" "No, my Lord, I never was," replied the Surgeon "Well, I am sure, Doctor, I can safely say, *you have cut a figure* IN THE TEMPLE."

THE METROPOLITAN WATER-SUPPLY. THE LONDON WATER BILL.

AT the sitting of the Joint Committee which was held on June 12th Lord BALFOUR of BURLEIGH presided.

On behalf of the Corporation of the City of London Lord ROBERT CECIL, K.C , was allowed to state the well known contention of that body, that it would be more just if payment for the supply of water were made by meter

Mr PEMBER, K.C., on behalf of the water companies, proposed that a schedule should be added to Clause 13 of the Bill to define the conditions under which the debenture holders of the companies were to be paid in water stock. The Committee rejected the proposed schedule but required that definite provision should be made as to the period of redemption of the water stock issued to the debenture holders and to the shareholders respectively, the period of redemption being fixed at 60 years in the case of the former and 30 years in the case of the latter

In regard to the matter of appeals from the arbitrators to the House of Lords—a matter which was considered at one of the earlier sittings—the Committee decided that an appeal should be allowed on a question of law should such leave be granted by the Court of Appeal, but not otherwise. The Committee further decided that "the Court of Arbitration should act in accordance with the decision arrived at in any such case." It was further provided that the Court of Appeal should have power to decide as to which party should pay the costs. On these points the decision of the Committee was unanimous, in spite of strong protests by Mr Pember who argued that the effect would be that the Court of Appeal would thereby be allowed to stereotype its own decision as the law of the land.

One of the water company directors succeeded in obtaining the insertion into the Bill of a special provision to the effect that he should on his retirement receive a pension equivalent *to two-thirds of the salary and emoluments received by him* during the two years next before the passing of the Act.

On June 13th the Committee finished their consideration of the Bill Lord BALFOUR of BURLEIGH again presided. A new clause was accepted to compel the Water Board to take over from the companies two chemists who are at present in their employ and that "for purposes of compensation" they should be deemed "*existing officers*" within the meaning of the Act.

A new clause was proposed by the Local Government Board to compel the Water Board to make provision for the chemical and bacteriological examinations of the water supplied and, further, to compel the Board to supply the necessary buildings, apparatus, plant, and staff to carry on such examinations efficiently

The clause was, after a division, accepted by the Committee, some less important amendments were dealt with, and finally it was ordered that the Bill should be reported to the two Houses of Parliament.

METROPOLITAN HOSPITAL SUNDAY FUND

THE following is a continued record of some of the principal amounts which have been received in aid of the Fund up to the time of going to press on Tuesday The total sum then amounted to about £28,000.

ASYLUM REPORTS

Cumberland and Westmorland Asylum (Annual Report for 1901).—The average number of patients resident during the year was 667, comprising 341 *males* and 326 females The admissions during the year amounted to 175—viz 100 males and 75 females Of these, 132 were first admissions Dr W F Farquharson the medical superintendent, states in his report that of the 175 patients admitted 155 were chargeable to the rates, 19 were private patients, and one was a criminal. The admissions included five cases of congenital imbecility, nine cases of epilepsy, five cases of general paralysis four chronic cases transferred from other asylums, and 10 patients who were over 70 years of age. In 27 cases among the admissions the attack of insanity had lasted over a year before the patient was brought to the asylum. "The great majority of the cases enumerated were incurable. More than one-half of the patients admitted came here in a feeble state of health; eight of these were extremely weak and exhausted and several died very shortly after admission." 50 of the patients admitted had suicidal tendencies and 24 of these had made actual attempts at suicide before admission. Hereditary predisposition to insanity was ascertained to have existed in 48 patients, or 27·4 per cent. of the admissions, and 31 cases, or 17·7 per cent., were attributable to alcoholic intemperance. "Where definite exciting causes of the attacks could be traced, there were in the great majority of instances diseases or disorders affecting the bodily health, mental shock being responsible for only a very small proportion of cases." The number of patients discharged as recovered during the year amounted to 96, or 14·5 per cent. of the average number resident. The deaths during the year amounted to 44, or 6·5 per cent. as calculated on the same basis. This death-rate was one of the lowest recorded in the history of the asylum. The mean age at death was 51·7 years. Of the deaths two were due to cerebral hæmorrhage, two to cancer of the uterus, four to organic dementia, four to pneumonia, four to senile decay, four to tuberculosis, six to general paralysis of the insane, nine to cardiac disease and its complications, and the rest to other causes. The cause of death was ascertained by post-mortem examination in every case. In five cases where the deaths were not attributable to tuberculosis evidence of tubercle was found post mortem. The general health of the patients throughout the year was good, epidemic or zymotic diseases having been absent. With the exception of three cases of fracture of bones, accidentally sustained, there were no serious casualties. The Commissioners in Lunacy state in their report that the patients were for the most part neatly clothed, contented, and orderly in behaviour, and that the medical case-books were kept in a manner creditable to the medical staff. The committee of management states in its report that a plan for the further purification of sewage by bacteria beds and earth filtration has been adopted, and that additional exits for escape in case of fire have been put up at the top of the main staircase and also on the first floor of Cumberland House which is a part of the asylum.

Leicester Borough Asylum (Annual Report for 1901).—The average number of patients resident during the year was 722, comprising 308 males and 414 females. The admissions during the year amounted to 408—viz., 118 males and 290 females. Of these 347 were first admissions. Dr. J. E. Montague Finch, the medical superintendent, states in his report that of the total number of patients remaining in the asylums at the end of the year—viz., 797—12 men and 17 women were deemed curable. "The health of the patients on admission in a great many cases was extremely enfeebled, many being brought to the asylum on an ambulance and requiring to be carried to bed, and no less than 10 died before they had been in the asylum a month." Of those admitted 22 were between the ages of 70 and 80 years and four were between 80 and 90 years of age. Among the chief causes of insanity in those admitted were hereditary influences in 35 instances, congenital defect in 10, alcoholic intemperance in 24, mental worry and adverse circumstances in 24, and old age in 10. The number of persons discharged as recovered during the year amounted to 72—viz., 28 males and 44 females, or 10·0 per cent. of the average number resident. The deaths during the year amounted to 54—viz., 33 males and 21 females, or 7·5 per cent. as calculated on the same basis. Of the deaths two were due to cerebral softening, three each to apoplexy and pneumonia, five each to congestion of the lungs and phthisis, eight to epilepsy, 13 to general paralysis of the insane, and the rest to other causes. Two cases of suicide occurred during the year, one from strangulation and the other from poisoning by corrosive sublimate taken before admission. A married woman was confined after admission and another married woman among the admissions was delivered of twins. The institution has been free from any disease of an epidemic nature during the year. A new extension of the building has been completed and the new wards were opened for male patients who were removed thither. The old male wards were altered and renovated in order to render them available for female patients, and they were all occupied before the middle of the year. The work of the nurses has been, adds Dr. Finch, exceptionally trying and arduous owing to the large number of admissions on the female side and the reorganisation of the wards. The Commissioners in Lunacy state in their report that the day-rooms were bright and comfortable and afforded ample accommodation, that the dormitories were well arranged and ventilated, and that the medical case-books were very well kept. The visiting committee of the asylum states in its report that in consequence of the increase in the number of female patients in the borough notice will be given to the proper authorities for the removal of a certain number of out-county patients. The expenditure on additions, alterations, and improvements cost £392 and on ordinary repairs £1200.

THE SERVICES.

ROYAL ARMY MEDICAL CORPS.

LIEUTENANT-COLONEL R. H. QUILL joins at Dover and takes up the duties of Principal Medical Officer of the South-Eastern district. Deputy Surgeon-General Don relinquishes his appointment as Medical Examiner of Recruits at St. George's Barracks in October next. Lieutenant-Colonel R. G. Thomsett takes up duty at Portsmouth. Surgeon-Lieutenant Taylor, A.M.R., is appointed to the medical charge of the Militia encamped on Middlewick, Colchester.

INDIAN MEDICAL SERVICE.

The King has approved of the following promotions among officers of the Indian Medical Service:—Majors to be Lieutenant-Colonels (dated April 1st, 1902): *Bengal Establishment:* Richard Havelock Charles, George Duncan, and William Ainley Sykes, D.S.O. *Madras Establishment:* Edwin William Reilly and James Scott. *Bombay Establishment:* Robert William Steele Lyons, John Patrick Barry, and Alexander Vass Anderson. Captains to be Majors (dated March 31st, 1902): *Bengal Establishment:* Allan James Macnab, Henry Smith, Charles Neil Campbell Wimberley, and Ernest Wickham-Hore. *Madras Establishment:* William Dunbar Sutherland, Percy Carr-White, Edmund Hassell Wright, William Molesworth, Clarence Forbes Fearnside, Charles Arthur Johnston, and Gerard Godfray Giffard. *Bombay Establishment:* James Jackson, Ashton Street, and John Bland Jameson.

The King has also approved of the retirement from the service of the undermentioned officers:—*Bengal Establishment:* Lieutenant-Colonel James Young (dated March 31st, 1902) and Lieutenant-Colonel Charles William Owen, C.I.E., C.M.G. (dated March 15th, 1902).

The above notification supersedes that of the retirement of Lieutenant-Colonel William Owen made in the *London Gazette* of March 20th, 1902.

ARMY MEDICAL RESERVE OF OFFICERS.

To be Surgeon-Majors (dated June 21st, 1902):—Surgeon-Captain W. B. Macdonald and Surgeon-Captain W. B. Mackay.

ROYAL NAVAL HOSPITAL, HASLAR.

The session of special instruction at the Royal Naval Hospital, Haslar, terminated on June 20th, when the following surgeons received appointments to His Majesty's ships. Two prizes—viz., the gold medal and microscope—were awarded to Surgeon Oswald Mills, R.N., late of St. Thomas's Hospital, and one—viz., the silver medal and £10 worth of books—to Surgeon Leslie M. Morris, R.N., late of St. Bartholomew's Hospital. Surgeons in order of seniority:—

Name.	Marks.	Name.	Marks.
Oswald Mills	5562	William N. L. Cherry ...	3863
Leslie M. Morris	5185	John G. Peebles	3790
Alexander K. Smith-Shand	4321	Thomas W. Myles	3788
Norman H. Mummery ...	4278	Elijah R. L. Thomas ...	3444
John Fullarton	4245		

THE WESTERN COUNTIES SOLDIERS' CONVALESCENT HOME, BATH.

The Duchess of Somerset has issued an urgent appeal for this excellent institution, which is situated at Combe Down, Bath. The home has now been in existence for two years and 170 patients have already been admitted. It appears that unless more funds are forthcoming the home is to be shortly closed. The authorities are anxious to keep it open until the end of the present year and for this purpose about £500 are required. The Soldiers' Aid Society has promised £200 on the condition that the remaining £300 are raised. The Duchess of Somerset has subscribed £100 and on

June 8th some of the Bath churches had collections for the fund.

Sir Joseph Dalton Hooker, G C S.I, C B, Surgeon R.N (retired) late Director of the Royal Botanic Gardens, Kew, has been presented by the German Emperor with the Order Pour le Mérite for his distinguished research in science and art.

Correspondence.

"Audi alteram partem."

THE DESTRUCTOR NUISANCE AT TORQUAY

To the Editors of THE LANCET.

SIRS,—It might have been thought that the frequent appeals for the establishment of open air sanatoriums would have gradually brought people to see that foul air is as great a menace to health as foul water or adulterated food Here, however, in a "health resort," where the only industry, as the Duke of Argyll once said, is "the manufacture of health"; the breezes which used to make the summer climate on the higher levels delightful now carry with them and cause to impinge upon various parts of the town the fumes from a refuse destructor, and in spite of all the representations made to the authorities, including those of the Special Commissioner of THE LANCET, no intelligent efforts have been made to deal with the cause of the nuisance which has just now entered upon its fourth summer Noxious matters issuing from the chimney of the destructor are weighed in the mental balance of the town councillors against noxious matters issuing from the kitchen chimney of a cottage and they find that the latter weigh the heavier When we consider that a cottage chimney would burn only a few pounds of coal, whereas the destructor burns some tons of refuse, we see that such a state inverts the arithmetical relations.

If we look at the chimneys under varying conditions we shall find the same singular inversion of facts On Sunday, for instance, the destructor does not work, whil t for the cottage chimney it is the busiest day of the week. Sunday, according to this proposition ought to be the day when the air is foulest. As an actual fact, it is the day which brings complete relief from the nuisance. Again, when the destructor is working but the atmospheric conditions permit of the ascent of the fumes, we complain of no pollution of the air This is notably the case in winter, the ascent being favoured by the greater difference which prevails at that season between the temperature of the fumes and that of the outside air In winter the cottage chimneys are active, in summer they are less so. In winter the destructor gives but little annoyance, in summer it is an abomination. Here, again, then, the facts of the case are turned upside down in the proposition. I do not know what the chairman puts into the scale against this and other facts. We have seen in Torquay some very striking effects of coal smoke, but they came from the town council's electric station, and happily they have now been completely remedied by the adoption of smokeless coal.

It has been suggested that potassium cyanide or arsenical fumes are present in the destructor products in appreciable quantities, but whether they are or not, the evils caused by the gases paraffins, and slags blown upon us produce effects which are unsatisfactory by products for a place whose object is "to manufacture health" Many of the inhabitants like myself, came down here to live as much as possible in the open air But in the summer time it is often impossible for us to remain in the garden—rather we are compelled to take refuge in the house and shut the windows. In former times the summers here were particularly cool and enjoyable. Now we are glad to spend as much of the summer as we can away from Torquay, even in places where the natural advantages are incomparably less favourable But all might be put right, as your Commissioner has clearly shown, and I feel that ultimately all must be put right. Should, however, the nuisance remain unmitigated through the present summer those interested in the great questions of the pollution of town air should not miss the opportunity of paying a visit to Torquay, when they will find an instructive object-lesson as to the results of placing the top of a chimney of a refuse destructor in the wrong place.—I am, Sirs, yours faithfully,

HENRY HUMPHREYS, M.A., M.D, Cantab.,
M R.C P Lond

Torquay June 14th 1902.

*** Owing to the great length of Dr Humphreys's letter we have been compelled to reduce it. The chemical considerations into which he enters in regard to kitchen chimney and destructor smoke are omitted. Obviously the two kinds of emanation show sharp differences in physical character and chemical composition which Dr Humphreys points out.—ED. L.

THE MEDICAL SERVICE OF THE MERCHANT MARINE

To the Editors of THE LANCET

SIRS,—I address to you this communication for the purpose of calling to the attention of my colleagues the present condition and prospects of seafaring physicians—ships' doctors of the merchant marine. In these days of keen competition and plethoric supply of medical men, who must consequently see their field of opportunity and financial prospects lessened, it seems only rational and business like that we should stand together and demand proper recognition and remuneration commensurate with the outlay of time and money which is necessary to fit us for professional duties. Physicians in private practice are repaid according to their skill and industry, and often by good fortune. Army and navy medical men receive fair recompense for their services, good social position, and prospects of advancement Too many physicians, however, all qualified, are giving their valuable time to hospitals, sanatoriums, and asylums for the niggardly salary of £50 to £150 per annum, which institutions carry heavy financial burdens but do not enable their medical officers to support a family The physicians, it must be admitted, have in some cases chance of advancement, which cannot be said of that most abject class of practitioners—steamship doctors.

Nearly every international passenger-carrying steamer of certain capacity is *compelled* to carry an officer, who is bluffed by the company into accepting for his services the pittance of £8 to £12 per month on English and American ships, £5 to £10 on German boats, and about the same amount when sailing under other flags, and as they are seldom allowed *to charge* a fee for their services their pay barely covers the cost of uniforms and other items of expense On American *ships their* position is humiliating as the engineers, dock officers as well as freight clerks receive better wages and are judged accordingly Unfortunately most steam-ship companies, *only* wishing to comply with law, are satisfied with any so-called doctor and there are always numbers of *professional* "scabs" who rent themselves out for a flunkey's salary It seems to me a disgrace that any qualified man should consider his services worth less than a guinea a day and I believe that if individuals and medical organisations *would* maintain their self respect and assert their rights by demanding that no position in a steam ship company, corporation, or institution of any kind be filled under £30 per month (which would support a family decently), they would soon gain their point and at the same time command the *respect* that educated physicians deserve They would be received at their own estimate and not ranked with "*unskilled* labour" It is well known that many young men go to sea merely for travel, but they should not give their time away any more than in civil practice for the physician's *time*, as well as actual services rendered must be considered.

The Spanish American doctors, although wanting in some respects, uphold their rights and refuse to accept less *than* £15 a month and a free hand in practice and *get it*, because they hold together and are difficult *to get at the* price mentioned, as they realise that their salary should be £30 instead of one-half of that amount. I trust that this subject will receive from the profession the attention that it deserves.

I am, Sirs, yours faithfully,
W T BURRES M D

TUMOURS OF THE STOMACH

To the Editors of THE LANCET

SIRS,—I have read the brief account in THE LANCET of June 21st, p. 1763, *of* the case under the care of

Mr. Mayo Collier, which is described as a "large malignant growth of the pylorus" treated by gastro-jejunostomy. May I venture to predict—and I think there is little hazard in the venture—that the case will prove to be, not one of malignant disease, but of chronic ulcer, of the stomach? As is well known, it is quite impossible to determine the character of any tumour in the stomach by inspection and palpation alone. The extraordinary accuracy with which the tumour resulting from chronic ulceration with induration may mimic the appearances in malignant disease has deceived such experts as Czerny and Kocher. Both these surgeons have removed portions of the stomach for supposed cancer and found on examination of the specimen nothing more than chronic ulceration and thickening. The history of Mr. Mayo Collier's case certainly gives support to my prediction. It is now three and three-quarter years since the onset of symptoms and the patient is in good and improving health. Five years before the operation the patient suffered from "peritonitis and inflammation of the bowels." May this not have been due to the perforation of a gastric ulcer causing peritonitis? At the operation "the pylorus with growth was firmly adherent to the liver and gall-bladder and the whole of the structures were matted together by old adhesions," precisely the condition that one would expect to find if perforation had occurred. Mr. Mayo Collier does not make mention of the chemical examination of the stomach contents, as to the presence or absence of free hydrochloric acid, or of lactic acid.

I have had under my care three cases considered to be malignant at the time of the operation but proved by the subsequent history to be instances of chronic ulcer with massive induration. The third case was sent to me in June, 1901, by Dr. Crawford Watson of Harrogate. A tumour of the size of a fist was felt in the abdomen; at the time of the operation a dense hard mass four inches in diameter occupied the isthmus of an hour-glass stomach. The tumour was firmly welded to the pancreas, was adherent to the liver and abdominal wall, and was therefore irremoveable. The cardiac loculus could not be reached because of the adhesions and I was therefore prevented from performing a gastro-enterostomy. I was compelled to be content with a retrograde dilatation of the stricture between the two sacs. With difficulty I passed my little finger through the centre of the supposed growth, then my index finger, and finally three fingers. The patient rapidly recovered from the operation and vomiting which had been the chief, and a most distressing, symptom entirely ceased. Before the operation the patient looked haggard, worn, and ill; she is now ruddy and plump; before the operation she weighed 4 stones 13½ pounds; she weighed when last seen 7 stones 7 pounds; before the operation she vomited after all food; now she can take any food in any quantity. I think that no one seeing the tumour when the abdomen was opened could have doubted its malignancy. Yet there is no trace of any tumour now I do not touch upon the question, which seems to be settled in the affirmative, as to whether veritable malignant growths in the abdomen or elsewhere are capable of spontaneous and complete disappearance. I am, Sirs, yours faithfully,

Leeds, June 21st, 1902. B. G. A. MOYNIHAN.

THE FEES OF MEDICAL WITNESSES.

To the Editors of THE LANCET.

SIRS,—Perhaps you will kindly allow me, as a near relation of Judge Greenhow, to make a few remarks on your leading article on "The Fees of Medical Witnesses" in THE LANCET of June 14th, p. 1702. In the first place you seem to me to err in thinking that the judge meant that the witness should give his evidence "gratis" or that there was any question of "gratuitous" services in the court; it was simply a matter of prepayment of the fee, as is plain from the expressions that he used: "It presses hardly upon poor people who have not several guineas to put down"; "You still persist in your intention of having the money laid down before you give evidence in this poor person's case?" "It seems to me an extraordinary line for gentlemen of the medical profession to take up, that they should require the money down." If, in the next sentence, as it is reported, the expression "decline to give evidence without fees" is made use of, it is plainly intended to be qualified by the same words with regard to fees as were used above—viz., "put down," "laid down," "money down." There may, no doubt, be solicitors who are given to "speculative" litigation or who refuse to pay their fees to medical and other witnesses, but that is no valid reason why the poor should be denied fair facilities for recovering, in the vast majority of cases quite legitimately, compensation for injuries; and, as the resident medical officers of our hospitals and dispensaries must from the circumstances of the case be almost always the principal witnesses, it would be practically a denial of justice if their evidence were permitted to be for any reason excluded.

Supposing the case of an accident to a workman occurring in the road through the mismanagement of a motor-car, the only witness of which is some gentleman other than a medical man. An action is brought by the injured man and the witness, who may be an engineer engaged in large practice, declines to take the oath or to give evidence till his fee is paid. That which he would say, if he chose, would certainly get a verdict for the workman, as the engineer happens to have practical experience in motoring and has formed a definite opinion on this particular case; what would be thought of his conduct if he refused to speak till his fee was given to him?

I entirely agree with you that when patients are too poor to pay the medical profession gives its aid ungrudgingly, and, I would add, with absolute unselfishness. I can therefore hardly believe that the medical witness depends, as a rule, for his fee on the success of the party on whose behalf he gives evidence. It may be so now and then, but probably only in very exceptional cases; whereas it is undoubtedly a constant thing that the resident medical officers of charitable institutions in our large towns are summoned in a perfectly honest way by poor litigants to speak in the court as to the facts connected with their injuries, and to throw obstacles in the way of such evidence being given appear highly undesirable.—I am, Sirs, yours faithfully,

H. M. GREENHOW.

Scotswood, Esher, Surrey, June 18th, 1902.

⁂ We maintain our views. Our leading article took int consideration all the circumstances which bring medical me into the witness-box in civil actions. These are entirel different to the imaginary case of the engineer witnessing a street accident which Mr. Greenhow suggests as a parallel Few are called upon to give evidence in such a case more than once or twice in a lifetime and their evidence is that o the ordinary citizen who by chance sees an occurrence ou of which a cause of action arises and is in a position to form an opinion as to the existence of the cause of action The medical man, on the other hand, by the nature of his profession, is constantly brought in contact with injured persons and his evidence has nothing or little to do with the cause o action if the injured person chooses to make his injuries the subject of litigation. There is absolutely no reason why th medical man should insist on prepayment for his services as a witness if he prefers not to do so, but there can be no jus reason for blaming him if he does so insist. He has as much right to decline to give evidence without prepayment, in ou opinion at all events, as a solicitor has to decline to accept the instructions of a client under the same conditions. The case of a medical witness may be better compared to that of an engineer, if we imagine the engineer to have had a complicated piece of machinery brought to him in order that he may advise upon its reconstruction after an accident or who has had an invention submitted to him by a stranger for advice as to its manufacture. If the engineer is subsequently asked to give evidence in an action to recover damages on the ground that someone had negligently injured the machine or in a lawsuit to determine the ownership of the inventor's patent, let him do so by all means if, and on what terms, he chooses. Let him, however, be at liberty to say: "My time is valuable, I prefer that it should be paid for, and I prefer the certainty of prepayment to the uncertainty of waiting, particularly in a case the merits of which I know nothing about." Mr. Greenhow has not, perhaps, had the same opportunities as ourselves of learning how hardly the present inadequate scale of remuneration presses upon medical witnesses and how often the medical witness is not paid for his services.—ED. L.

PINEAPPLE AS A DIGESTIVE AID.

To the Editors of THE LANCET.

SIRS,—The value of the pineapple as a proteid digestive I can fully confirm, not only from personal experience at the table but also from experiments in vitro. Its active principle, bromoline, has long been used in the preparation of Mosquera's beef jelly, a most satisfactory extract, but, unlike most ferments, owing to its instability the commercial preparation of bromoline has, I believe, so far proved unsuccessful. The reputation of the pineapple has suffered for many reasons; far too much is eaten at a time and the fibrous part is swallowed as well as the juice. To obtain its full digestive value one quadrant of a moderately (say half an inch) thick slice is ample for one meal; it should be well masticated and the fibrous part rejected. As justly remarked it must not be cooked and it should be just ripe. My experience is that the preserved form has practically no digestive power.

Apart from its being an aid to digestion it has a powerfully solvent *action upon plastic exudation*—e.g., diphtheria membrane. This is easily demonstrated by exposing a portion of the membrane or some white blood clot to the action of the juice in a flask, when under favourable conditions of temperature and movement it will soon be dissolved. When, however, *applied to the throat*, either as a "swab" or spray, in a case of diphtheria, the contact is so short that one cannot expect extensive solution, but it will be found to exert a decidedly softening effect on the sticky and stringy exudation so as to admit of its easy *detachment*. Again, too, its solvent power is well shown upon thick and horny epidermis in a manner similar to salicylic acid, although *somewhat slower in action*. If a thin slice of fresh pineapple be kept in close contact with a corn for eight hours it is so softened as to admit of ready removal. Likewise it softens the horny papillæ in keratosis of the tonsil and rapidly relieves the "pricking sensation." Pineapple juice has evidently wide therapeutic possibilities but for whatever purpose employed it must be borne in mind that the fresh juice alone can be relied upon.

I am, Sirs, yours faithfully,

WYATT WINGRAVE, M.D. Durh.

Devonshire-street, W., June 7th, 1902.

CANNABIS INDICA IN CHOREA AND PERTUSSIS.

To the Editors of THE LANCET.

SIRS,—Early this year I was called to see a—to me—record case of chorea. The patient, a bright girl, aged 11 years, was suffering from her third attack in five years. I tried increasing doses of Fowler's solution with apparent success, but in a fortnight she was frightened by a steam fire-engine dashing past the house at night and the next morning I found her flinging her arms and legs about with such violence that they were severely bruised against the back and legs of the couch on which she lay. Fearing death from exhaustion I put her on opium, of which it required from three to four grains a day to control the muscles. Then the appetite failed and she had in addition a severe attack of toothache, necessitating the removal of an upper molar under gas, which was only administered with great difficulty. This operation again intensified the movements and I resorted to Indian hemp, giving her seven and a half minims of the tincture made from Parke, Davis and Co.'s fluid extract every four hours. The effect was magical. Next morning she was lying composed on the couch, looking perfectly happy, with only slight muscular twitching and appetite improving. In three weeks she could dress and feed herself without much assistance and has now been for over two months strong and well. While attending this case I was called to one of pertussis in a boy, aged 22 months. The cough was almost incessant and accompanied with vomiting. I gave him two minims of the tincture of cannabis indica every three hours. The next day I was told he had a very good night, coughing only three times. On the third day the cough had almost ceased and by the end of a week had disappeared. In a second case shortly after, that of a girl, aged five years, I gave five-minim doses every four hours. After the second four-ounce mixture had been finished the mother told me the girl only coughed slightly about once a day. She took no more medicine and is quite well. In all three cases the following points were noticeable: (1) direct relief to spasm, (2) absence of any head symptoms, and (3) non-interference with appetite or digestion. I may add that only a little chloroform water was added to the tincture to conceal the slightly unpleasant taste and that the mixture was well taken in each case.

I am, Sirs, yours faithfully,

Birmingham, June 20th, 1902. E. T. BURTON.

INSANITY AND THE DEATH PENALTY.

To the Editors of THE LANCET.

SIRS,—I think that the above subject is one of great importance and I agree with most of the remarks in the leading article in your issue of June 21st, p. 1782. I wish, however, that you had more strongly condemned the practice adopted at some of these trials—i.e., to consider a criminal insane because the court shrinks from the capital sentence. By all means, if the public conscience is averse to capital punishment, let it be abolished, but it is not right that some murderers should suffer the penalty of the law and others get off on the score of insanity who, in the eyes of all except certain "experts," are fully as sane as the former. At the present time it might be fairly argued that all murderers are insane at the time they commit their crimes. In the majority of criminals of the more brutal type, by examining their past history it is not unlikely that a condition of "minor epilepsy" might be diagnosed. This may be all very well from a psychological point of view, but it is questionable whether it tends to the public safety. I cannot help thinking that the law, as laid down in the McNaughton case, and which is still the law, was far sounder for protecting the public than that inspired by "the tendency towards mercy natural to advancing civilisation." A man makes improper proposals to a barmaid, accompanied by a pecuniary bribe, and on her refusal shoots her. He is exonerated on the ground of "minor epilepsy." A few years ago a girl, aged 19 years, was convicted of murder at the Hertford Assizes and executed. Her crime was the sending poison to an imbecile sister at a public asylum, which the latter unfortunately partook of, and was apparently prompted by an idea that she would obtain by her sister's death a small sum of money in the Savings Bank. Surely, as good a case of insanity might have been made out there. It is more than likely that during the last two years criminals have been executed in this country quite as insane as Simmons.

The object of all punishment is to deter. If it has not this effect it is useless. In the case of an undoubted lunatic it can have no deterrent effect and no good is gained by its infliction. But can it be affirmed with any certainty that punishment would have no deterrent effect on criminals whose insanity depends on the niceties of expert evidence? Might not the punishment of criminals like Simmons tend to make others of his class keep their illicit passions more under control? I cannot help thinking that the safety of the public lies more in that direction than in striving on humanitarian principles to prove every murderer insane in order to escape the penalty of the law.

I am, Sirs, yours faithfully,

M. GREENWOOD, M.D. Brux., LL.B. Lond.,

Hackney-road, N.E., June 21st, 1902. Barrister-at-Law.

THE LONG FOX MEMORIAL.

To the Editors of THE LANCET.

SIRS,—At a meeting held in the Chapter House of Bristol Cathedral on May 29th the following resolution was unanimously adopted:—

That a memorial be established to the late Dr. Edward Long Fox and that it include: (1) the placing of a tablet in the cathedral; (2) the founding of an annual lecture at University College, Bristol, in some subject connected with medical science to be called "The Long Fox Lecture"; (3) the partial supporting of a medical missionary student at University College, Bristol, to which the balance of the fund collected will be devoted after providing for (1) and (2).

We shall be glad to receive any contributions from friends of the late Dr. Fox.

We are, Sirs, yours faithfully,

W. W. ASQUITH, 34 College-road, Clifton;
E. MARKHAM SKERRITT, Edgecumbe House, Richmond Hill, Clifton.
} Honorary Secretaries.

June 21st, 1902.

SANITATION ON THE RIVIERA: WHAT WILL BE DONE DURING THE SUMMER?

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

THIS is the moment for carrying out public works and effecting general improvements at the various winter stations of the Riviera. The visitors have gone, the greater number of the hotels are closed, and the permanent inhabitants are willing to endure some personal inconvenience if it will help to increase the golden harvest which they hope to reap when the winter season comes round once more. What with the South African war and the prevalence of small-pox the number of visitors was far below the general average last winter. Now, however, the war is over and it remains for the local authorities to push forward their various schemes for sanitary reform so that small-pox and typhoid fever may not once again frighten away intending visitors. If this is achieved there is good reason to hope that the next season will be a great improvement on that of last winter. But there is much to be done and it is not possible for more than a partial improvement to be realised between this and the end of the autumn. For instance, the water-supply of Nice and of some neighbouring towns is insufficient and unsatisfactory. The authorities at Nice cannot press the householders to abolish their cesspools and to drain directly into the sewers because there is not enough water to ensure the satisfactory flushing of the closets. The main supply is from the Vésubie mountain and it is distributed at Nice, Monaco, and elsewhere. Whether this water is absolutely safe for drinking purposes is an open question. Favourable analyses of the Vésubie supply have been published and yet an increase in the number of cases of typhoid fever was noticed following upon a heavy rainfall, and this has occurred more than once. But a heavy rainfall by choking up the sewers occasions an extra escape of air from badly-ventilated sewers into dwellings which have imperfect systems of interception. Without attempting to discuss this question in its complex bearings it is safe to say that the various municipalities concerned should unite to carry out some vast scheme for the improvement and increase of their water-supply. The offshoots of the Alps stretch far behind these towns. There are mountain torrents and splendid gathering grounds for the collection of pure water but the cost might be too great for any one town to bear. An association of towns dividing the initial expenses would render the most ambitious schemes practicable.

At Nice the sewers used to drain into the sea at the nearest convenient point. Consequently the sea front was more or less contaminated by these sewer outfalls. Now the outfalls of the old town, to the east of the river Paillon, which divides the town into two parts, are received in a large main collector. A syphon has been constructed under the bed of the Paillon, and the sewage from the east is thus carried over to the western side of the town, and here it falls into the sea by the one general outfall close to the pier. But this again is a serious inconvenience, as the pier faces the best part of the celebrated Promenade aux Anglais. Fortunately, this grievance may now be considered as a thing of the past. A main sewer has been built all along the sea front with a fall far away to the west and in the month of July the present outfall will be closed. Henceforth the sewage will be thrown into the sea about a mile and a half to the west and beyond the limits of the town. Another improvement awaits the visitors for next season. During the summer months 150 new street gullies will be put in position. These gullies are made of hardware, but contain metallic sand collectors that can be easily lifted out, and the sand, leaves, and other impedimenta can be promptly and frequently removed. Many times it has been thought that bad odours came from the sewers, whereas the nuisance was caused by the accumulations within old-fashioned and badly-constructed street gullies. If, together with these measures, vaccination is more widely enforced and suitable accommodation is provided for the isolation of patients suffering from infectious diseases there will be less hesitation on the part of visitors to spend the next winter at Nice.

In the Principality of Monaco the principle directly into sewers, which involved the abolition o was adopted and proclaimed by a decree which date of June 23rd, 1894. But a long time must elapse between the acceptance of a principle and i application. In many parts of the principality to be built, and there was this difficulty, that th the low-lying district of the Condamine had their outfall in the Bay or Port of Hercules. Th was close to the bathing establishment and objectionable. To meet the difficulty two Shone 500 gallons capacity have been employed. These sewage to a higher level, whence it can flow main sewer that passes behind the Rock of Monaco falls into the sea to the westward of the old town, can cause no inconvenience. Without entering technicalities of the drainage scheme of th pality there are still at least two importan that should, and that could, be immediately The one is that there yet remain some hou are not connected with the sewers and that the old and barbaric system of cesspools. the sewers themselves are inadequately ventilate large chimneys, or shafts, have been placed at th levels, but these are altogether insufficient. Be ventilators and at lower levels there are numerous flushing tanks. This is all very well so far as the cle the sewers is concerned, but the water as it ru presses the air forwards, while the ventilators are How, then, is the air to escape if not by breaking t seals of the traps? It stands to reason that v should be in front of the flush tanks as well a them. A strong, sudden flush will draw the air d the ventilator that is behind and push it out throug ventilator that should be in front.

Then, it is well known that ventilators only act portion of the sewer that is in their immediate n hood, whereas at Monaco some parts of the se about half a mile away from one of the four ve M. Tschirret, who is in charge of much of th work which in an English town would be [illegible] the borough surveyor, proposes to introduce a pip the dip-trap of the street gullies. These pipes, ope the roofs of the nearest houses, would become s sewer ventilators. But some householders might ob that case the dip which forms the water seal of the gully might be removed and the sewer would then into the street on a level with the roadway. If th are self-cleansing and ventilated throughout there s no nuisance. If there is a nuisance then [illegible]s clear sewer is not in a satisfactory condition and must be The object of sanitation is not to convey a bad odour point or altitude where it will not be noticed, but t all that may cause such a bad odour. Actu principality is remarkably free from any such un ness, and notwithstanding the defects just mentio one of the best drained places on the entire Riviera. done so much it is only natural to expect that the au will not neglect these minor imperfections but will s them remedied.

There is no lack of enterprise at Monaco, nor does of expense hold the authorities in check. Thus in with the disposal of household refuse the Govern the principality did not hesitate to incur the n outlay to build a destructor. The Horsfall syst adopted. This system precludes the admission of directly upon the furnace. Such air is warmed first by through heated channels outside the furnace. The ducts of combustion also are brought back un fire, and the soot, dust, &c., are thus destroyed. means the nuisance that might result is reduc minimum. As a further precaution the destructor i in an isolated position and only worked at nig has four cells and can consume 54 cubic metres o in 24 hours, but the refuse is not of a nature th burn unaided. It is necessary to add coke Fortunately this can be obtained from the g and the gas administration is credited with five for every ton of coke powder which it provides destructor. This, however, is a misleading calcula the commercial value of the coke powder is about 1 the ton, so that the destruction of the refuse rea more than it appears to do. Though the clinkers ash from the destructor are utilised or sold and b and, still it is felt that the present method of dealing refuse is too expensive and researches are being find some more economical mode of proceeding. In while, and so far as the public is concerned, the t remains that domestic refuse is collected every promptly destroyed by fire This is the safest of the problem and the inhabitants of the prin- ow know nothing of the dustbin grievance which the source of so much trouble in many parts of itain.

ld be difficult to quit the subject of Monaco without word about the Casino. Great as has been the pro- omplished in regard to sanitary matters throughout lpality, the old-standing grievance of the inefficient on of the Casino still survives. This want of ventila- ore particularly felt in the gambling rooms. Much as been spent to enlarge and to beautify the Casino. have cost much less to provide efficient ventilation. improvement achieved of late years in this respect the substitution of electric for gas light, and this, is quite insufficient. Medical practitioners are still to warn their patients against Monte Carlo, not for fear of the gambling—facilities for gambling rywhere—but because of the overheated atmosphere mbling rooms at the Casino. It is difficult to under- y this matter has been neglected so long while enterprise has been shown in other respects. Still, pite of these criticisms, Monaco and Monte Carlo he most popular resorts of the Riviera. Natural climate, art, and sanitary science all combine to be principality of Monaco the most attractive spot whole of the Riviera. The sanitation is not yet ut it is better than that which exists in other orts.

fferent, for instance, is the situation of Cannes. stem of drainage was planned and its execution d many years ago, but it has never been com- The sea front is still contaminated by the outfalls erous sewers. Houses continue to drain into cess- here has been much talk but nothing effective has . An excellent water-supply runs daily risk of being ated because it is brought to the town in an open that passes through populated and highly cultivated Typhoid fever made its presence felt once more he last season. Still nothing is done. In one however, which especially concerns the visitors, fortunately situated: there is a British cottage with English trained nurses and 14 beds for the of medical and surgical cases. Then, in the grounds surrounding this villa or cottage there is n with seven beds for the isolation and treat- infectious cases. Here no distinctions are made ard to creed. Then there is also a French t charity called the Asile Évangélique, where, only Protestants are admitted. This institution an annexe for the bath treatment of typhoid fever. ottage hospital called Sunny Bank the patients are from 5s. to 10s. a day, but there are four endowed occupants of which are treated gratuitously. There- ish or American visitors are not dependent on the hospital if suffering from some disease that cannot d in the lodging, the villa, or the hotel where they residing. In this respect the foreign colony at as set a good example which, as has been seen, the d American winter residents at Nice are striving to

res considerable hopes of improvement are enter- cause the Government has decided to convert this, and oldest winter resort of the French Riviera, rrison town. Barracks are now in course of con- and it is thought that they will increase the revenues. According to the present disposition nicipality one of the first things that will be done e construction of an isolation hospital for infec- es. But, even as matters now stand, Mr. Biden e that he never encounters any difficulty with his atients. If a case of scarlet fever, or any other fever, occurs, he at once interviews the hotel and insists on an immediate and definite decision t is to be done. He points out that the patient must at once removed or allowed to remain for the whole of the illness. If the patient is to remain then he indicates what measures of isolation must be strictly enforced. If not, the patient is removed to one of the private rooms available at the general hospital. An English trained nurse is called in to attend to the patient and Mr. Biden continues his visits at the hospital instead of at the hotel Of course, the patient pays for his maintenance at the hospital and obtains the diet and medicaments which his private medical adviser thinks fit to prescribe. Thus, at Hyères, the friendly coöperation between the municipal authorities who administer and own the public hospital and the British medical practitioners is an accomplished fact and seems to work satisfactorily As yet no progress has been made with regard to a general scheme of drainage for the town of Hyères and it is to be feared that some time must elapse before the means are found to carry out public works of this description. The main difficulty rests in the divided interests of the inhabitants. There are two parties at Hyères. One represents the interests of the hotels, the lodging-house keepers, and the tradesmen, the other party represents the market gardeners who supply the northern markets with early fruits and vegetables. The members of the latter party do not care in the least about sanitary improvements and other public works calculated to increase the number of visitors. In these circumstances it will be very difficult to get a vote in favour of an expensive drainage scheme. But now that the presence of a large number of soldiers will cause the Government to take an interest in the sanitary condition of Hyères it is thought that the municipality will be compelled to devote more attention to such matters. In any case, this is the season when all these questions must be pressed forward. When the hotels are empty, when the wealthy visitors are away, and all these winter resorts seem to be asleep in the blaze of the summer sun, the time has come to dig up the streets, to lay new sewers, to empty and to close up the old cesspools, and to carry out all such public works.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Maghull Epileptic Institution: Opening of the "Harrison" Home.

A NEW home in connexion with the Maghull Epileptic Institution, called the "Harrison" home, for the benefit of first-class patients, was formally opened on June 14th. The cost of erecting and furnishing the spacious building was defrayed by Mr. Frederic James Harrison, the president of the institution. The new building stands in the park of the old Manor House estate at Maghull and is beautifully surrounded, as, indeed, the whole institution is In 1889 the Manor House was opened as a home for people suffering from epilepsy and in the first year 22 patients were treated Subscriptions then amounted to £57 and the committee received in donations the sum of £2332. From that time onwards the usefulness of the Insti tution has been recognised In 1895 the "*Henry Cox*" home was added and the number of inmates had increased to 117 Two years later a building known as the "Iron Hall" was opened, this erection being used for indoor recreation and other purposes. Last year "Chapel House" was added, the patients then numbering 136 (70 males and 66 females) The institution is now divided into three classes—first, second, and third. The patients are afforded all kinds of amusements and congenial occupation, chiefly outdoor. The new home is well provided with comforts On the ground floor there is a spacious dining room, also a drawing room and a billiard room, all facing the park. Dr. William Alexander. on receiving the new home on behalf of the committee, said the gift of Mr Harrison was a princely one. He thought that institutions like theirs were invaluable. Epileptic patients never had a chance with private treatment. Even if attendants were provided for them their lives were not happy ones, either the attendant obtained the upper hand or else the patient did so, and that was not as it should be so In the new home patients would be amongst their own class; and when they were removed from their own homes and surroundings he had always noticed a remarkable change for the better in their condition. The treatment carried out at Maghull was quite different from that adopted in private practice The new home was intended for the better classes, and there they would be sure of obtaining proper treatment

---

[1] See THE LANCET, May 17th, 1902, p 1428.

Dr. J. M. Rhodes (Manchester) in seconding a vote of thanks to the medical officers of the institution, said that the institution was of immense value not only to Liverpool, but to the world at large. Last year he paid a professional visit to the United States of America in connexion with epilepsy and had discovered that the Maghull Epileptic Institution was well known there through the name of Dr Alexander. He thought that the public of this country did not sufficiently acquaint itself with, and interest itself in, the terrible ailment of epilepsy. The Registrar-General's report last year gave the number of deaths from epilepsy as 2597. He thought that the State ought to take up the question of epilepsy by providing suitable homes for those so afflicted and not leave it so much to private charity and philanthropy. In America special homes were provided for epileptic patients, instead of their being allowed to live in the workhouses, and in this country something similar might be attempted.

June 20th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

By-laws Prohibiting Spitting.

THE county councils of Glamorganshire and Brecknockshire have each taken advantage of the provisions of the Local Government Act, 1888, which enable county councils to make by-laws for the "good rule and government of the county" and have drafted a by-law prohibiting spitting in public carriages, churches, &c.[1] Before the by-law can be enforced it must receive the sanction of a Secretary of State, and the Home Secretary has written to the Glamorganshire County Council to the effect that the by-law cannot be made to apply to churches, chapels, schools, and shops, but he will allow it to come into force if its operation is confined to public carriages, public waiting-rooms, public halls, and places of public entertainment. The by-law prohibits spitting on the "walls or sides," as well as on the "floor," of these places.

The Alfred Hughes Anatomical Museum.

When the late Professor Alfred Hughes left Cardiff in 1897 to join the staff of King's College he gave £350 to the Cardiff University College for the purpose of providing an anatomical museum and when it was decided, shortly after his death in 1900, to establish some memorial of his work in Cardiff the most proper course appeared to be to endow permanently the museum which he had created and to which he had contributed most valuable diagrams and specimens. This course was adopted and the endowment fund now amounts to £1666. The trustees of the fund will each year present a medal to the most successful student of the college in the department of anatomy. The medal has been designed by the Welsh sculptor, Mr. W. Gascombe John, A.R.A., and was presented on June 20th to Mr. R. K. Shepherd, B.Sc. The museum was formally opened on this date by the President of the Cardiff College, Mr. Alfred Thomas, M.P., who also presented to Mrs. Alfred Hughes the first copy of the medal.

South Wales and Monmouthshire Branch of the British Medical Association.

The thirty-second annual meeting of this branch was held at University College, Cardiff, on June 20th, under the presidency of Dr. A. P. Fiddian of Cardiff, when Dr. R. G. Price of Carmarthen was elected President for the ensuing year. There are now 265 members attached to the branch and the balance-sheet discloses a balance in the treasurer's hands of over £100, notwithstanding the fact that £38 15*s.* were sent last year to the British Medical Benevolent Fund—a charity which has always received substantial support from this branch. For the past two years one meeting of the six held yearly has been devoted to medico-ethical matters.

The late William Howell Lloyd, M.R.C.S. Eng., L.S.A., Deputy-Coroner for the Eastern Division of Carmarthenshire.

Mr. William Howell Lloyd of Llandilo, Carmarthenshire, died suddenly from heart disease on June 13th, at Swansea, whilst on a visit there. The deceased received his medical education at Guy's Hospital and qualified M.R.C.S. Eng. and L.S.A. in 1869. He shortly afterwards settled where he soon acquired an extensive practice. was medical officer of health of the Llandil urban districts and surgeon to the Great Western Company. He was also deputy-coroner for th division of Carmarthenshire and surgeon-captai 1st Volunteer Battalion Welsh Regiment. Mr. L extremely popular in the district and much sympa for Mrs. Lloyd and the six children. At the fune took place on June 18th, a very large number of were present.

June 23rd.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The British Medical Association and the Au Natives Association in New South Wales.

THE differences between the New South Wales the British Medical Association and the Australia Association (to which reference has previously b are increasing. It is now a case of *guerre à l'outr* April 3rd a largely attended public meeting wa protest against the action of the branch. The taken by the President of the Australian Natives A who in the course of his address stated that the British Medical Association was taken with the "smashing all the friendly societies in the State said, "the friendly societies were going to stand sh shoulder and had the public sympathy with them. had not to fight the whole medical profession b small section of it." The general secretary of the Natives Association then made a statement of The Australian Natives Association was regist friendly society on Dec. 3rd, 1900, and in 1901, the secretary of the New South Wal of the British Medical Association inquired if tralian Natives Association would impose a w of £200 per annum on its members so far as medic were concerned. He was told that the associati not do so. A conference was then held between r tives of the two associations and finally a comm was received that the British Medical Associati considered the Australian Natives Association " prejudicial to the interests of the profession" Fol this the medical men who had anything to do Australian Natives Association were ostracised. A of further negotiations the Australian Natives A intimated that a reasonable wage limit would be with a graduated scale of payments by the patient above the sum allowed annually by the associat British Medical Association declined the propos Australian Natives Association withdrew the offe not intend to renew it. If the British Medical A persisted in its present tactics the Friendly Societie tion would use the means at its disposal for the ment of medical institutes throughout the St following motions were carried:—

> That this meeting is of opinion that the action of the Wales branch of the British Medical Association in boy A.N.A. is unjustifiable, unreasonable, inconsistent, and therefore unworthy of public support, and that the acti that body is with the avowed intention of striking a death existence of all friendly and benefit societies.
>
> That in the opinion of this meeting it is inimical to the i of friendly societies to recognise the action of doctors belon B.M.A. in fixing a wage limit, which, if countenanced, wi disadvantage of friendly societies generally.

In proposing the last motion the President of th Societies Association stated that the friendl membership in New South Wales was 80,000 and £70,000 were paid annually to the medical offic societies could not afford to lose those members w receipt of annual incomes over £200. They were t intellect and knowledge in the societies and cont membership not for personal benefit to themsel the assistance they could give. He proposed as a r the present difficulty the formation of a medical their own with a capital of £100,000. The secret New South Wales Branch of the British Medical A has written to the press denying that the Associat to "smash up the friendly societies" and pointin the Australian Natives Association is on a totall bacillus which in its cultural characteristics corresponded generally with bacillus mesentericus vulgatus. From the spleen a growth of a bacillus corresponding with the last was obtained and diplococcus pneumoniæ was not isolated from this organ. In sections made through the substance of one of the "mulberry spots" and stained for bacteriological examination no bacteria of any sort could be found. In sections made through the coats of the stomach and the overlying false membrane two kinds of bacteria could be recognised. There were considerable numbers of bacilli which were probably of the same species as that isolated in culture, and also a number of cocci arranged in isolated pairs and in small colonies which stained by Gram's method showed a distinct tendency to diplococcal arrangement, were in many cases surrounded by a distinct capsule, and in all respects corresponded with diplococcus pneumoniæ as it is seen in animal tissues. These bacteria were seen principally in the exudation membrane and in the immediately subjacent necrotic tissue; only a few could be found in the submucous connective tissue and then only just below the muscularis mucosæ.

---

[1] THE LANCET, March 22nd (p. 851) and May 10th (p. 1361), 1902.

The strain of diplococcus pneumoniæ isolated was of comparatively low virulence for rabbits; two animals received by intra-peritoneal injection medium doses of a 48 hours' old culture in broth and recovered after a temporary illness.

General histological examination.—In sections through the wall of the stomach it was seen that the changes chiefly affected the glandular structure of the mucous membrane. On the surface there was a fibrinous layer of considerable thickness beneath which the glandular layer of the mucous membrane had undergone an extensive necrosis, in some places down to the muscularis mucosæ, so that frequently no recognisable trace of tubular structure remained. In other places the deeper portions of the glands retained their general structure, but the lining epithelium was cloudy or disorganised. Small masses of altered blood pigment were scattered throughout the mucous membrane and quantities of apparently unaltered red blood cells could be seen lying both within the lumen of the glands and free in the interglandular connective tissue. Below the muscularis mucosæ the submucous connective tissue layer appeared to be but slightly thickened; the spaces of the connective tissue were somewhat enlarged, as if after distension by a serous effusion; and there were largish masses of homogeneous yellowish brown pigment scattered about, especially in the neighbourhood of blood-vessels. The muscular coat showed very little change; here and there were masses of altered blood pigment resembling that seen in the submucous layer. One notable point in the histological examination was the very slight evidence of any inflammatory reaction. In the submucous coat there was no indication at all of such reaction, and in the muscular coat there were only a few collections of leucocytes at wide intervals.

A consideration of the pathology of the case suggests that the primary lesion was perhaps a pneumococcic infection of the right tonsil, though this was not proved. The infection of the stomach then resulted from the swallowing of the parasite, and the general infection followed the invasion of the stomach. The healthy stomach, with its strongly acid secretion, would in all probability be an extremely unfavourable site for the growth of diplococcus pneumoniæ, and it is not unlikely that a certain amount of gastritis resulting from the swallowing of fœtid pus from the ulcer on the tonsil was a necessary preliminary to the pneumococcic invasion of the gastric mucous membrane.

The absence during life of any vomiting is noteworthy, the more especially as there was no indication after death of any distension of the viscus which would have suggested paralysis of the muscular coat.

The pathological changes in the stomach in this case form a strong contrast to those in the case of phlegmonous gastritis due to streptococcic infection described by Dr. W. Cayley[3] in which whilst the surface epithelium and glandular layer of the mucous membrane were hardly at all affected there was great thickening of the submucous connective tissue coat, the result of a purulent infiltration. I have said that I have not been able to find any previous record of a case of this sort, but Dieulafoy in a lecture on *gastrite ulcéreuse pneumococcique*[4] has described a condition which is probably a later stage of a similar lesion. Dieulafoy's case was that of a man, aged 35 years, who was admitted into hospital with a history of pain in the side for seven days past. On admission a diagnosis of pneumonia on the right side was arrived at, but there were also very marked abdominal symptoms in the way of pain, diarrhœa, and vomiting. Two days after admission there was a severe attack of hæmatemesis, followed by the appearance of blood in the stools, and again hæmatemesis; the patient died on the fourth day after admission. At the examination after death evidence of a general pneumococcic infection was found, pneumonia on the right side, pericarditis, and peritonitis; the specific coccus was isolated from all these lesions. On opening the stomach it was seen that the mucous membrane presented a number of small erosions, either round or oval in shape, and with a diameter of from two to three millimetres. The erosions were especially numerous near the pylorus, and as many as 10 or 12 could be counted in a square centimetre of the mucous surface; many of them had a small blood-clot at their base. Dieulafoy describes the lesions in his case as consisting of an erosion of the whole thickness of the glandular layer of the mucous membrane down to the muscularis mucosæ, due to a rapid and localised necrosis of the areas affected. There was little or no inflammatory reaction in the tissues in the neighbourhood of the erosions. In sections a large number of diplococci could be seen both in the interglandular connective tissue and within the capillaries, the distribution of the cocci being general and not limited to the immediate neighbourhood of the erosions.

It is extremely probable, then, that Dieulafoy's case simply represents a later stage of a lesion such as was found in the case which I have described; in the latter case, if the patient had lived long enough for the exudation membrane and the necrosed portions of the mucous membrane to be thrown off it is probable that a condition of ulceration similar to that which Dieulafoy describes, but perhaps on a rather larger scale, would have resulted.

Dieulafoy also refers to another condition of the stomach occurring in the course of a pneumococcic infection. The patient, a man, aged 45 years, was admitted into hospital with signs of pneumonia on the left side; subsequently there were indications of peritonitis and an acute arthritis of the left wrist. At the examination after death the diagnosis of pneumonia was verified; there were three interlobular abscesses in connexion with the left lung, purulent meningitis, peritonitis, suppurative arthritis of the left radio-carpal joint, and vegetations on one of the aortic valves. The presence of diplococcus pneumoniæ was demonstrated in these lesions. On opening the stomach a number of hæmorrhagic patches were seen in the mucous membrane and in the submucous connective tissue. In the mucous membrane these hæmorrhagic patches were situated just below the surface and there was no sign of inflammatory reaction around them. Bacteriological examination of the wall of the stomach gave no results.

This second case referred to by Dieulafoy probably represents a different condition of things to that prevailing in his first case and in my own. In the two latter cases there is the result of a local infection of the mucous membrane from without by swallowing; in the other the change is probably merely one of the general effects of a pneumococcic blood infection in which, whether occurring naturally in man or induced artificially in experimental animals, there are to be found sometimes petechial hæmorrhages into the skin and the mucous and serous membranes.

Apparently closely allied in its pathology to the ulceration of the stomach described by Dieulafoy is the case of ulceration of the colon recorded by Rathery and Chauffard.[5] The patient was a man, aged 51 years, who was admitted into hospital with pneumonia at the right base. After admission there were three attacks of profuse hæmorrhage from the bowel and the patient died on the thirteenth day of his illness. At the examination after death a double pneumonia was found. The mucous membrane of the ascending colon was coated with blood and there were blood-clots in the transverse and descending portions. Scattered over the mucous membrane were punctiform hæmorrhages and at the junction of the transverse and descending portions there were five or six superficial ulcers, each with a diameter of from one to two millimetres. There were similar ulcers at the from the other societies; it aims at including all of Australian birth, irrespectively of financial posi- d all such could claim medical benefits at the same other friendly societies and that according to the f the Government statist the proportion of Australian the whole population is as four to one. It would dal for the medical profession to contract to attend h at the rates current with friendly societies which riginally instituted by wage-earners for wage-earners re unable to pay ordinary medical fees. On 23rd, the Australian Natives Association held its conference in Sydney and the opportunity was to discuss the action of the medical profession. nual report gave a statement of what had occurred was resolved that the matter should be left in the hands board of directors to deal with, and the past action of rd in its dealings with the British Medical Association nfirmed. In discussing these resolutions the members emphatic in their condemnation of the medical pro- and in their determination to fight the matter out break up what they termed an "unholy conspiracy" It was further stated was very close to an "infraction law." It was also suggested that medical men should ght out from the United Kingdom to act as medical

Medical News.

IETY OF APOTHECARIES OF LONDON.—At ations held in June the following candidates passed subjects indicated:—

ry.—E. W. C. Bradfield (Section I.), St. Mary's Hospital; H. B. ko (Section I.), St. George's Hospital; G. W. C. Hollist tions I. and II.), Guy's Hospital; G. J. Humphreys (Sections I. II.), St. Bartholomew's Hospital; E. Osborne (Section II.), mingham; F. H. Rotherham (Sections I. and II.) London spital; E. M. Stacy (Sections I. and II.), Royal Free Hospital; J. Taylor (Sections I. and II.), Bristol; W. P. Taylor, Sheffield Bristol; J. Vaillant (Sections I. and II.), Paris; and F. W. B ng (Sections I. and II.), Leeds and Liverpool.

cine.—W. Ball (Section I.), Westminster Hospital; T. G. Long- f (Section I.), Oxford and St. Thomas's Hospital; A. Mooney ction I.), Royal Free Hospital; C. C. Morgan (Section I.), St tholomew's Hospital; E. C. Pratt, Birmingham; and E. M. cy (Sections I. and II.), Royal Free Hospital.

sic Medicine.—W. Ball, Westminster Hospital; J. C. B. Dunn, Bartholomew's Hospital; T. G. Longstaff, Oxford and Thomas's Hospital; S. J. Meredith, Birmingham and London spital; A. Mooney, Royal Free Hospital; E. C. Pratt, Birming- m; and E. M. Stacy, Royal Free Hospital.

ery.—L. Courtauld, Cambridge and Middlesex Hospital; E. Darlington, Birmingham; H. B. Drake, St. George's Hos- al; E. Gray, London Hospital; B. Hirsch, Berlin; T. G ngstaff, Oxford and St. Thomas's Hospital; E. M. Stacy, Royal e Hospital; H. S. Tumber, Sheffield; and P. L. Vawdrey, Bartholomew's Hospital.

diploma of the society was granted to the following candidates, g them to practise medicine, surgery, and midwifery:—H. B. gton, E. Osborne, E. C. Pratt, F. H. Rotherham, E. M. Stacy, aylor, and W. P. Taylor.

IVERSITY OF CAMBRIDGE.—At examinations dical and surgical degrees, Easter term, the following lates were successful:—

FIRST EXAMINATION.

I. Chemistry and Physics.—P. H. Bahr, Trinity; C. T. V. King's; H. S. Berry, Clare; T. R. H. Blake, Pembroke, W. A. Bull, B.A., Caius; L. S. T. Burrell, Trinity; H. J. B. , Caius; J. R. C. Canney, Christ's; W. J. Carr, Trinity; S P. , Caius; F. Clayton, Trinity, H. N. Coleman, Christ's; F. S. Collier, Pembroke; R. M. Collinge, Caius; D. Cotterill, rist's; A. J. W. Cunningham, Trinity; L. T. Dean, Sidney sex; H. Deardon, Caius; G. H. Dunn, Pembroke; W. H. F. les, Emmanuel; A. Fergusson, St. John's; C. L. Forde, Clare; D. Fox, Trinity; H. G. Frean, St. John's; D. J. Freyer, Trinity; S. Gibson, Emmanuel; H. D. Gillies, Caius; W. Harmens, A. Hett, and G. A. P. Heyworth, Trinity; C. J. R. Hoffmeister, ius; F. H. Holl, Trinity; H. E. Humphrys, C. H. T. Ilott, B.A., H. R. Ingleby, Caius; W. F. Jones, King's; H. N. Little, ius; R. S. Lound, H. Selwyn; M. F. J. McDonnell, St. John's; Mackenzie, Emmanuel; A. G. M. Mainwaring, Trinity, D C. ster, Caius; A. H. Moore, Trinity; A. Morgan, Corpus Christi; Nicholls, non-collegiate; B. K. Nutman, Jesus; W. G. rkinson, Emmanuel, B. A. I. Peters, Jesus; F. S. Poole, Sidney ssex; R. C. Priest, Caius; C. E. Redman, Pembroke; L. W. arp, G. L. Siddle, and C. R. Smale, Caius; F. H. Smith, rist's; E. R. Stone, Emmanuel; C. H. S. Taylor, C. Tylor, and St A. Vivian, Caius; R. H. Walker, St. John's; H. W. S. lkee and H. K. Waller, Trinity; J. F. Windsor, H. Selwyn; . Wood, Pembroke; S. Wood, Christ's.

II. Elementary Biology.—P. H. Bahr, Trinity; C. T. V. Benson d H. Bowring, King's; J. R. C. Canney, Christ's; R. S. Carey, rpus Christi; W. J. Carr, Trinity; S. P. Chan, Caius; R. C. ance, Trinity; H. Chapple, St. John's; L. Colledge, Caius, G. Collett, Trinity; H. F. S. Collier, Pembroke; R. M. Collinge, Caius, H. M. McC. Coombs, Emmanuel; A. J. W. Cunningham, Trinity; L. T. Dean, Sidney Sussex; H. Deardon, Caius; M. Donaldson, Trinity; W. H. F. Eales, Emmanuel; F. S. Eschwege and A. W. Ewing, Christ's; A. Fergusson, St. John's; N. M. Fergusson, Magdalene; L. A. Fothergill, Emmanuel; H. G. Frean, St. John's; D. J. Freyer, Trinity; H. D. Gillies, Caius; C. D. Hawthorne, Clare; T. R. Hodgson, Christ's; G. Hoffmann, Caius; G. N. Humphreys, Catharine; H. R. Ingleby, Caius; G. James, St. John's; W. M. Jeffreys, B.A., Trinity; N. W. Jenkin, Christ's; W. F. Jones, King's; A. R. Jordon, Clare; J. L. Joyce, King's; H. F. Lester and R. L. Ley, Pembroke; H. N. Little, Caius; R. S. Lound, H. Selwyn, M. F. J. McDonnell, St. John's; C. Mackenzie, Emmanuel; R. G. Markham, Caius; L. Meakin, Trinity; L. Nicholls, non-collegiate; W. Oats, Caius; R. Parker, Christ's; W. G. Parkinson, Emmanuel; B. A. I. Peters, Jesus; F. S. Poole, Sidney Sussex; A. V. Poyser, Magdalene; R. C. Priest and K. D. Pringle, Caius; J. H. Roberts, B.A., Emmanuel; C. F. Searle, Pembroke; S E. T. Shann, L. W. Sharp, G. L. Siddle, and A. L. H. Smith, Caius; F. H. Smith, Christ's; H. C. Snell, Caius; R. M. Soames, Trinity; P. A. Stockdale, Magdalene; E. R. Stone, Emmanuel; A. C. Tait, Sidney Sussex, C. H. S. Taylor and O. Teichmann, B.A., Caius; G K Thorpe, Clare; C. St A. Vivian, Caius; G. Walker, Trinity; V. T. P. Webster, Emmanuel; J. N. Wheeler and T. M. O. Williams, Christ's, W. H. Winter, Caius; and S Wood, Christ's.

SECOND EXAMINATION.

Part II. Human Anatomy and Physiology.—E. D. Anderson, B.A., Pembroke; E. E. Atkin, Caius; A. S. B. Bankart, B.A., Trinity; S. Barradell-Smith, B.A., St. John's; E. Bell, B.A., Clare; H. A. Browning, B.A., St. John's; A. D. Brunwin, B.A., Trinity; A. S. Burgess, B.A., Caius, G. H. U Corbett, B.A., King's; R. M. Courtauld, B.A., Pembroke; G. L. Cox, B.A., and H. F. Curl, B.A., Christ's, L. G. Davies, B.A., Trinity; H. S Dickson, B.A., and A. H. Fanlon, B.A., Christ's; G. S. Haynes, King's; T. W. S. Hills, B.A., Downing; G. Holroyd, B.A., Christ's; W. G. Howarth, B.A., King's; C. L. Isaac, B.A., St. John's, C. S. Lee, and A. S. Little-johns, B.A., Caius; M. McPherson, B.A., and W. P. Morgan, M.A., Clare; W. H. Newton, B.A., Emmanuel; W. M. Orton, B.A., Trinity; H. B. Owen, and P. R. Parkinson, B.A., Caius; F. Shingleton Smith, B.A., King's; K. S. Singh, B.A., Pembroke; E. C. Sparrow, B.A., Trinity; C. M. Stevenson, B.A., St. John's; R. S. Taylor, B.A., Down; F. J. Thornton, Caius; F. C. Trapnell, B A, and A. Wilkin, B.A., King's.

UNIVERSITY OF DUBLIN: TRINITY COLLEGE.—At examinations held at the School of Physic, Trinity term, the following candidates were successful:—

Final Examination in Medicine.—John S. Joly, John A. Valentine, Robert P. Beatty, Horace Townshend, M.D., Ernest B. Booth, Walter R. H. Smith, Charles M. Benson, James E. Johnston, Richard F. Steel, Wallace Benson, Harry F. Johns, John S. Wilson, George R. Harman, William A. G. Cluffe, and George H. Keene.

M.B. Degree.—William H. Pelle M.R.C.S Eng., William Taylor F R.C S.I., and Herbert L. Thurnell, M R C.S. Eng.

AT the recent annual meeting of the American Laryngological Association in Boston, on May 27th, Dr. StClair Thomson was elected a Corresponding Fellow.

THE ROENTGEN SOCIETY.—The annual general meeting of this society will be held on July 3rd, 1902, at 20, Hanover-square, London, W., at 8.30 P.M.

THE Worshipful Company of Fishmongers has given a grant of £21 to the funds of the After Care Association for Poor Persons discharged Recovered from Asylums for the Insane. This is a piece of well-placed charity. We wish we could chronicle similar occurrences often.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

Cremation Bill.

THIS Bill now awaits the Royal assent, having passed through all its stages in both Houses of Parliament. It enables burial authorities to establish crematoria and regulates their construction and management.

Midwives Bill.

The second reading debate on the Midwives Bill in the House of Lords brought out very clearly that several members, and notably the Lord Chancellor, entertain serious objection to the measure. It may therefore be taken that when the Committee stage is reached efforts will be made to amend the Bill. At present the Committee stage stands in the orders of the House for Friday, July 4th, though, of course, it is possible that it may not be taken on that day. Seeing that the first subsection of the first clause was substantially altered during the report stage in the House of Commons it will be of service to state its terms. They are: "From and after the first day of January, 1910, no woman shall habitually and for gain attend women in childbirth, or shall after the first day of January, 1905, be entitled to take or use the name or title of midwife (either alone or in combination with any other word or words) or any name, title, addition, or description implying that she is certified under this Act or is a person specially qualified to practise midwifery or is recognised by law as a midwife unless she be certified under this Act."

HOUSE OF COMMONS.

MONDAY, JUNE 23RD.

Kennedy Town Plague Hospital.

Mr. WEIR asked the Secretary of State for the Colonies whether he was aware that there was only one physician in charge of the Kennedy Town Plague Hospital, Hong-Kong; and, in view of the requirements of the patients, whether he would consider the expediency of calling for a report on the subject with a view to a larger and better trained staff being provided for this hospital.—Mr. CHAMBERLAIN replied: The staff of the Kennedy Town Hospital for infectious disease, which is, I am told, within easy reach of the civil hospital, includes a resident medical officer, two trained European wardmasters, and two trained sisters. According to the latest returns the total number of beds is 28, and the daily average of cases in hospital less than five. Under these circumstances I see no necessity to interfere with the arrangements made by the Colonial Government with the advice of the Principal Civil Medical Officer.

The Belfast Small-pox Hospital.

Mr. T. W. RUSSELL asked the Chief Secretary to the Lord Lieutenant of Ireland whether he was aware that it was proposed to erect a small-pox hospital for Belfast within the asylum grounds at Purdysburn, county Down; that there was an industrial and agricultural population in the immediate neighbourhood, and that objection had been taken to the erection of the hospital; and if he could state what the medical officers of the Irish Local Government Board had decided to be the striking distance of small-pox contagion, and if the asylum itself and the homes of the people were outside the distance.—Mr. WYNDHAM replied: The site of the temporary small-pox hospital is on lands acquired by the Belfast corporation for asylum purposes, but which were subsequently allocated to hospital purposes by the City of Belfast (Hospitals) Act of 1893. The site is 300 yards from the nearest dwelling-house. Some objections have been received by the corporation to the erection of the hospital. Neither the Local Government Board nor their inspectors have prescribed any fixed limit as the striking distance of small-pox contagion.—Mr. RUSSELL asked whether the right hon. gentleman was aware that the striking distance of small-pox contagion was clearly laid down by the Local Government Board in England and whether two national schools and a large number of cottages were within the striking distance as laid down by the Local Government Board in England.—Mr. WYNDHAM said: I am not competent to speak with regard to the English Local Government Board. As to the other question the only alternative would be to keep the patients in the workhouse hospital.—Mr. RUSSELL said that as considerable alarm existed in the neighbourhood perhaps the right hon. gentleman would inquire as to the rule and its working in England.—Mr. WYNDHAM undertook to make inquiry.

MIDWIVES BILL.

DEBATE IN THE HOUSE OF LORDS: FULL REPORT.

ON Friday, June 20th, the Midwives Bill was read a second time in the House of Lords.

The Duke of NORTHUMBERLAND, who had charge of the Bill, moved the second reading. He said that he would not make a long speech because he thought that there was a general consensus of opinion in favour of something being done to remove the evils of the existing state of things in this connexion. The Bill had been before their lordships upon a former occasion and then had a favourable reception at their hands. There were in this country between 10,000 and 15,000 women practising as midwives and they were said to attend annually 450,000 cases of labour to which no medical man was called. Yet there was absolutely no guarantee that these women were efficient for the work that they undertook. It was possible that any old drunken hag with no idea of cleanliness, no acquaintance with proper methods of conducting this work, might advertise herself as a midwife and carry on her practice without let or hindrance. If their lordships were to examine the reports of coroners' courts they would find a melancholy but very instructive lesson as to the necessity for a Bill of this kind. Of the 250 coroners in England and Wales more than 200 had signified their approval of some such measure. A curious fact had come out in connexion with the Bill—namely, the prevalence of puerperal fever in certain districts. This was a preventable disease and in the hospitals of London it was now practically unknown, yet in certain districts it was on the increase rather than the decrease. Not only were deaths caused by the present state of things, but a very large amount of suffering, sickness, and disease was inflicted upon mothers and children. In blind asylums it was calculated that 40 per cent. of the cases of blindness were due to want of care at birth. All these things justified an attempt at a remedy and he could not wonder that the question had been attacked over and over again in both Houses of Parliament. No doubt in matters of detail the question was fraught with many difficulties and in asking their lordships to pass the second reading he did not ask them to assent to every sentence in the Bill. He frankly admitted that it was a Bill which required very careful consideration in detail, and he trusted that their lordships would give it that consideration when it reached the committee stage. He asked their lordships now to assent broadly to the principle that in order to secure the proper degree of knowledge which was required by midwives, and also to secure that the character of midwives was good, some kind of certification ought to be carried out. They were face to face with a difficulty which had caused much heartburning in former years but which, he thought, was fairly met by this Bill and that was to secure the position of existing midwives, those who were really fit for their duties and whose character was beyond reproach, of whom, of course, there were a very large number. These midwives were safeguarded by the Bill and he trusted that they would suffer no inconvenience in their practice. When the Bill was introduced before great exception was taken to the fact that there was no sufficient local control. Now that had been amended by giving the county council a large power of supervision within its area. He had no reason to suppose that opposition to the Bill at this stage would be offered and therefore he would conclude by asking their lordships to pass the second reading.

Lord WELBY said that while he had no wish to impede the progress of the Bill he desired to draw attention to the fact that very considerable powers were given to an independent body described as the Central Midwives Board. This board would be entitled to draw [illegible] paid by candidates for certification for its expenses, but if [illegible] of expenses remained it would fall as a charge upon the [illegible] aware that the expenditure of the board was to be approv[illegible] Privy Council, but he would call their lordships' attention [illegible] that the approval came after the expenditure had been [illegible] therefore that the control must be very imperfect. It was [illegible] usual thing to allow one body to spend money and then [illegible] bill to another body without any check over the expendi[illegible] thought, therefore, that provision should be made for contro[illegible] stantial kind, and he recommended the subject to the consid[illegible] the promoters of the Bill.

The LORD CHANCELLOR said that he had some more [illegible] jections to the Bill. He did not undertake the responsibility [illegible] the rejection of the measure because there might be cases [illegible] by the Bill which required regulation. He could not help think[illegible] the persons who prepared the Bill had in mind large centres [illegible] tion possessed of ample means of obtaining medical assistance [illegible] entirely omitted to consider the position of country distric[illegible] it was difficult to get even trained nurses. It was a sort of [illegible] with which it was all very well for people in London and [illegible] of population to deal so lightly. The circumstances of [illegible] districts were, however, quite different. He had received [illegible] dence from magistrates in no less than five counties [illegible] Worcestershire, Warwickshire, Sussex, and Surrey, all telling [illegible] story. He was told that if the Bill in its present form w[illegible] into law it would inflict an inconceivable amount of [illegible] and suffering upon the poor in rural districts. [illegible] also written to him and it appeared to him that she [illegible] a very strong case against the Bill. This lady had herself [illegible] examination and got a certificate, not in order to make a li[illegible] midwife, but merely for the purpose of assisting the poor, and [illegible] her knowledge she protested against the Bill. She said th[illegible] cases out of 1000 a technically untrained woman was quite [illegible] all the assistance necessary and that the woman called [illegible] acted as nurse, washed the baby, and performed dome[illegible] vices, and that to compel a poor man's wife to pay [illegible] for a trained midwife or a doctor was a foolish piece [illegible] lation. There were certain passages in the letter which per[illegible] cated a measure of jealousy of the medical profession, but there [illegible] no doubt that the lady was thoroughly acquainted with the [illegible] One of the magistrates to whom he had referred wrote saying [illegible] its present shape the Bill would inflict great hardship upon poo[illegible] in rural districts where wages were low and there were few [illegible] for providing trained and certified midwives. The habit of poo[illegible] he said, was to employ a woman for 7*s*. 6*d*. or 8*s*. 6*d*. a week [illegible] only attended the mother in her confinement but also looked [illegible] house generally. They were respectable persons, he add[illegible] did work which trained nurses would not do. Their [illegible] would notice that it was proposed to postpone the opera[illegible] the penal provision for eight years. That was [illegible] colourable amendment. The condition of things eight [illegible] hence in the country villages would not be different from [illegible] it was now. The supposition apparently was that the wom[illegible] begin to train themselves between now and eight years he[illegible] amendment was merely a colourable one and, indeed, was n[illegible] ment at all. He could tell their lordships that persons well [illegible] forming a judgment looked upon the Bill in the present [illegible] very serious reflection upon the working population, and why [illegible] thought it right to say so much upon the matter was that [illegible] not going to move the rejection of the Bill he did not want t[illegible] pass without their lordships' attention being called to the [illegible] might arise from its application in its present form so that [illegible] got into committee they might look into the matter with [illegible] care in order to see that no such injury was done to the poorer [illegible] as these correspondents said would be done.

The Bishop of WINCHESTER said that it was appropriate that [illegible] remarks on this subject should come from the episcopal [illegible] because of the close connexion which had historically existed [illegible] the persons referred to in this Bill and the members of the [illegible] bench. He did not know whether their lordships were aware [illegible] fact that for many centuries no woman could practise the [illegible] of midwifery without the direct sanction of the bish[illegible] the diocese. That might sound like a relic of very far [illegible] days, but he might say that within the lifetime of [illegible] of their lordships, bishops sent out inquiries to the cl[illegible] learn whether or no the midwives engaged in practice wer[illegible] licensed. This, however, was a mere curious incident in the [illegible] this matter, a story which was the more remarkable the mor[illegible] looked into it for the wide swing of the pendulum from one [illegible] another. At one time the subject of midwifery was very little [illegible] by the medical profession. He believed that he was right in [illegible] that down to even the early part of last century it was treated [illegible] College of Surgeons in a very much less respectful manner [illegible] other surgical matters. Now, however, the pendulum had swung [illegible] opposite direction. There were some among those who oppos[illegible] who went so far as to speak of the midwife as a person who pr[illegible] ought not to exist at all, who was an absolute anachronism [illegible] promoters of the Bill did not take either of these extreme views. [illegible] recognised, of course, the paramount necessity that in all or[illegible] circumstances there ought to be a ready appeal, at all events [illegible] trained medical man wherever it was possible, but whilst they [illegible] gnised that they also recognised the natural and wholesome i[illegible] which led so many mothers to prefer the aid of one of [illegible] own sex whom they had reason to believe to be fairly [illegible] qualified for the task. It was calculated that 60 per [illegible] of the births in England took place without the [illegible] of a medical man. Whilst they recognised this desire, reas[illegible] natural, and wholesome, they wished to do something which [illegible] secure that the women who performed these functions had [illegible] some degree of competence and were under some sort of super[illegible] In this respect England was not quite abreast of other countr[illegible] France there had been legislation since 1803, in Belgium since [illegible] Austria since 1810, and so on, and we, almost alone among the [illegible] of Europe, had trusted simply to the general judgment and com[illegible] sense without interfering except in cases of extreme wrong. The [illegible] the matter was looked into the more would be apparent [illegible] need for some training for the exercise of this craft [illegible] evidence which came before the commission of which he was a me[illegible] on infant life protection as to the mischief which took place from ance of those who were professedly giving such help as was had impressed itself upon the mind of practically all the of England and no small number of the medical profession. h the doctors were not by any means agreed as to the way in the wrong ought to be set right, he thought he was speaking ly when he said that they were unanimous as to the exist- very great wrongs in things as they stood. It had been evidence that from 25 to 30 per cent. of the cases that had ated in hospitals for women and children were due to mis- ment at the time of childbirth. That was no small matter surely sufficient to call for very determined intervention part of the Legislature. There was the particularly hard case girl-mothers who in their time of dire trouble were compelled aid. What had these girls—and their number was enormous— In the columns of certain newspapers there were advertise- by the dozen offering homes for them. These homes were the supervision of a midwife. These were not illegal or un- ry. Something of the kind there must be, but surely [illegible] needed supervision more than the people who kept [illegible] They could not close these houses but they could [illegible] precautions surely to prevent the worst forms of [illegible] n. He had followed with all the care he could the that fell from the Lord Chancellor. He was not quite that he understood the grounds upon which the writers of the read by his lordship based their objection to the Bill. It almost to him that they had overlooked the words in the clause as to now engaged in the practice of midwifery. The clause dealt omen who habitually and for gain attended women in child- It had nothing to do with the friendly neighbour who came in e her help and the benefit of her experience, but only dealt with man who made it her profession to do something which in some e was ill qualified to do. At present there was no means of g this woman and he believed that no greater help could be given poorer classes than to pass some such Bill as this. The Lord llor had said that the Bill must have been drawn by people who familiar with the rural districts and who only knew the cities e centres of population. Now it happened that the Member in of the Bill in the other House (Mr. Heywood Johnstone) was the ntative of an extremely rural district—namely, the Horsham n of Sussex. The proposal now made to postpone the time when ral provision came into operation did not seem to him quite to the criticism of his lordship. He understood that the object of rangement was to allow women for a time to go on practising. as, first of all, for the sake of the public, because it was impossible all at once to get a supply of qualified , and in the second place they did not wish to press hardly be women now in practice. It was inevitable that there should e little difficulty, but it seemed to him that it had been got over amendment in the way to cause least harm and least friction. ped that the Bill would not only be read a second time but issue from the committee stage in a form not very much nt from the present shape.

Russell said that the success of the measure would depend much on the way that the Central Midwives Board carried out the entrusted to it. For himself he did not see why this legislation cause midwives to raise their charges very much. He was glad that women were to be members of the board, because he was that their services would prove to be of the greatest value. s of opinion that the Bill demanded general support, though it be necessary to amend it in some particulars in committee.

Thring criticised points of detail in the Bill.

Balfour of Burleigh said that they were all matters which be dealt with in committee. Seven years ago he had moved the reading of a Bill on this subject, but when he entered the ry he had refrained from taking any further part in the movement legislation. It had, however, his cordial support and he was o find that there was now so good a prospect of the Bill passed. There was no intention [illegible] ere suddenly with those are qualified to practise as midwiv[illegible] t of the Bill was to that women who acted as midwiv[illegible] sufficient know- and training to know when to ca[illegible] assistance. He was ent that the better a woman was [illegible] eadier would she be gnise danger and call in this assi[illegible] approved the Bill as portant and far reaching measure, [illegible] storm.

Duke of **Northumberland** said that [illegible] strongly sympathised all that had been said about the position of poor people in rural ts. Any Bill which put them in a worse position than they were n in times of trouble would not be a Bill which their lordships pass. But what did the Bill say? It said, first of all, that no n should habitually and for gain attend women in childbirth properly certified. Then it went on to say in Clause 2 that any n who within two years from the date of this Act coming into tion claimed to be certified should be certified if she held certain cates or produced evidence that at the passing of the Act she had for at least one year in *bonâ fide* practice as a midwife and that re a good character. This provision, he thought, satisfactorily be case.

Bill was then read a second time.

OYAL COMMISSION ON ARSENICAL POISONING.

Experiments with Rats.

e Royal Commission on Arsenical Poisoning held a meeting for amination of witnesses on June 13th in the Westminster Palace , Victoria-street. Lord **Kelvin**, chairman of the Commission, ted, and the other members present were Sir William S. Church, William Hart Dyke, M.P., Professor Thorpe, and Dr. A. B. White- , with Dr. G. S. Buchanan of the Local Government Board, tary.

. **Otto Hehner**, representing the Society of Public Analysts, and **Alfred Chapman**, representing the Society of Chemical Industry, evidence as to the work of the committee appointed by these two to find out the best processes for the detection of arse[illegible] and malt and the approximate estimation of minute quantities of that poison. The committee recommended the Marsh-Berzelius test, and both gentlemen submitted reasons for its adoption. Given pure materials for the test they said that it was easy to use even by inexperienced people and that it gave accurate and reliable results with a minimum of tro[illegible]. They both preferred it to the Reinsch test.

Professor S. **Del[illegible]pine** of Owens College, Manchester, then presented to the Commission the results of his experimental investigation upon the action of arsenical beer and other arsenical solutions administered in large quantities to rats. The objects of the investigations were to ascertain—1. Whether the presence of arsenious acid in beer could account for the changes observed in persons who had consumed arsenical beer. 2. Whether it was necessary to assume that a compound more poisonous than arsenious acid was present in arsenical beer. 3. Whether the presence of organic compounds of arsenic such as cacodylates could account better for the effects of arsenical beer than the presence of arsenious acid. 4. Whether the quantities of arsenic found in beer by chemical analysis were sufficient to account for the effects produced by arsenical beer. 5. Whether the presence of alcohol in such amounts as are usually present in beer so favour the pathogenic action of arsenic as to render minute doses of that poison exceptionally noxious. 6. Whether concurrent influences, such as insufficient diet, could account for the different effects of arsenical beer upon different individuals. Rats were specially suitable for the experiments because they took beer and weak watery solutions of alcohol and arsenious acid very readily and could adapt themselves to considerable variations in their diet. They were less affected by arsenic than man and many other mammals. In man doses of arsenious acid varying between 0·1 gramme and two grammes had been known to produce death. A dose of two grammes to a man of moderate weight—i.e., weighing about 63,000 grammes—was equivalent to a dose of 0·003 gramme per 100 grammes body weight. Rouyer had found that arsenious acid or arsenites administered to dogs by the mouth was fatal in doses of 0·006 gramme per 100 grammes body weight (a dose of 0·015 gramme or arseniate of soda was necessary to produce the same result). Such a dose usually produced death in 24 or 48 hours. In rats he had found that a much larger dose was necessary to produce death in four and five days. A single dose of 0·012 per cent. of body weight produced the death of a rat weighing 135 grammes in four days. Two doses each of 0·006 gramme per cent. of body weight administered to another rat weighing 141 grammes produced death in five days from the giving of the first dose. From these results it would appear that the lethal dose of arsenious acid administered by the mouth might be for rats at least twice greater than the lethal dose for dogs and four times greater than the lethal dose for man. These figures were necessarily only approximate, especially with regard to man, but they were none the less useful in forming an opinion upon the value of the results obtained in experiments on rats. Thus, in trying to estimate the probable effects of certain quantities of arsenical beer upon man he had thought it desirable to administer to a certain number of rats solutions containing at least four times more arsenic than he had found in the most contaminated beers examined by him during the outbreak. He had, however, also used doses smaller than those actually taken by many beer-drinkers. Most of the beers he had examined contained less than two grains of arsenic per gallon. In one case he had found over one and half grains of arsenic per gallon. The largest quantity of arsenious acid he gave to rats for ordinary experimental purposes was seven grains per gallon, the fluid being given at the rate of one gallon a day for a man weighing 140 pounds. The quantity of beer taken by sufferers had frequently exceeded one and two gallons daily—i.e., from 7·14 per cent. to 14·22 per cent. of the weight of a man weighing 140 pounds. He had administered the arsenical beer or solutions in quantities equivalent to 8 per cent. or 16 per cent. of the body weight of the experimental animals, the slight excess being allowed as a compensation for accidental unnoticed losses. The experiments were conducted in sets. In each set a certain number of rats were placed under conditions absolutely identical. All the cages were of the same size and shape, placed side by side in the same part of the room, so as to be at the same temperature and receive the same amount of light. All the rats were fed at the same hour in the morning and were weighed just before being fed. The first set of experiments seemed to indicate that—(1) solutions of arsenious acid in water acted in the same way as arsenical beer; (2) that arsenical beer was less injurious than watery solutions of arsenic of the same strength; (3) that when an animal was well fed the presence of a small quantity of arsenic did not affect its health seriously for a time; (4) that doses of arsenic much greater than those found in arsenical beer capable of causing symptoms of chronic arsenical poisoning might be taken for about one month without causing death but that death was liable to occur suddenly at the end of such a period; (5) that after arsenical beer had been taken for a period of over three months the sudden stoppage of that fluid might be attended with disturbance of health causing serious loss of weight. The outcome of the second set of experiments seemed to be that arsenical beer, containing only a trace of arsenic, even in presence of an amount of alcohol above the average, was not very injurious to the health so long as a large amount of food was taken. The presence of a large amount of arsenic was clearly injurious whether alcohol was present or not, but the presence of a large amount of alcohol seemed in this case to precipitate the fatal issue. As in the first set of experiments, he observed that the replacement of the arsenical beer by pure water was not always attended with a beneficial result. The third set of experiments showed that beer containing arsenic derived from arsenical glucose, used as a malt substitute in brewing, was apparently as injurious as finished beer to which pure arsenious acid had been added. Cacodylate of sodium had apparently no bad effect and seemed even to be beneficial. Beer free from arsenic and containing a small amount of alcohol was distinctly beneficial and apparently acted as a food. The chief outcome of the fourth set of experiments was that alcohol when given in small doses together with arsenic did not seem to intensify the bad effects of the latter; there was, on the contrary, an indication that alcohol retarded the action of arsenic. During the preliminary stages of the experiment Rat 14 increased in weight more rapidly than Rat 15 and yet at the end of the experiment Rat 14 had lost weight to a greater extent than Rat 15 which was taking arsenic along with alcohol. The fifth set of experiments had for object to determine the lethal dose of arsenious acid. He had already indicated the results. The sixth set of experiments confirmed his impression that bitter beer drunk at the [illegible] of the outbreak in Salford and in Manchester was less whol[illegible] than lager beer imported from Munich. Whether this diffe[illegible] attributable to the small trace of arsenic present in the [illegible] between the products of high and low fermentation he was [illegible] yet to say, but his general impression was that beer brewed at a low temperature was more wholesome than beer brewed at a high temperature. It was also to be noted that the bitter beer used in this set of experiments was beer which would have passed easily the test recommended by the brewers' commission. In the seventh set of experiments the animals showed fr[illegible] evidence of intoxication, so that the administration of a fluid containing 26 or 20 per cent. of absolute alcohol produced [illegible] which were not observed in rats to which an equal [illegible] alcohol was given in a more diluted state. The effects of alcohol were also more variable than those of arsenic. Two of the [illegible] to recover gradually from the first effects of alcohol and to [illegible] weight, two other rats continued to lose weight from the first. Only one of the four died, and that animal seemed from the first to be very sensitive to the action of alcohol; possibly it was not in a good state of health at the beginning of the experiment. After the death of most of the rats used in the experiments a post-mortem examination was made and the chemical estimations revealed clearly the fact that the amount of arsenic present in the body after death bore some relation to the amount of arsenic taken during life. The evidence, so far as it went, seemed to indicate that arsenic might accumulate in the tissues up to a certain point. That the tissues were not capable of retaining more than a certain amount of arsenic seemed also to be indicated by the fact that whenever large doses of arsenic were administered, even up to the time of death, the amount of arsenic found in the body after death was invariably smaller than the amount of arsenic given daily. These results seemed to indicate that arsenic formed some kind of compound with tissue elements. Another interesting fact was brought out by these estimations. Arsenic was found in the tissues of two rats which had ceased to take arsenic for more than 40 days before death. In Experiment 1 the amount found was nearly equal to a daily dose. In Experiment 6 the amount of arsenic found was 16 times greater than a single daily dose. The daily dose in this case was exceedingly small. To account for these results it was almost necessary to suppose that arsenic entered into combination with some of the constituents of protoplasm. When large doses were given it was probable that a portion of the arsenic passed out of the body with the fæces and that a portion of what passed into general circulation, not being retained by the tissues, was excreted by the skin, liver, kidneys, and other glands. This view was supported by actual observation in the human subject. He made several attempts to collect the urine and fæces of rats taking arsenical fluids but he was not successful in devising a plan excluding the possibility of contamination of the excreta with the fluid administered to the animals. Generally speaking, the results of the estimation of arsenic in the experimental rats confirmed the view that arsenical beer, such as was drunk during the outbreak, acted in the same way as solutions of arsenious acid containing about the same quantity of arsenic as those which he had estimated to be present in that beer. Watery solutions of arsenious acid appeared, however, to be more toxic than beer containing the same amount of arsenic. Professor Delépine then dealt with lesions found after death in rats which had taken arsenic and compared them with lesions observed in persons who had died from the effects of arsenical beer. On the basis of his preliminary examinations he might say that the following changes were of common occurrence among the victims of arsenical beer—viz., (1) general hyperæmia, most noticeable in the lungs, glands, muscles, and nerve centres; (2) considerable degeneration and wasting of some of the muscles examined; (3) albuminous and fatty degeneration of the cardiac muscle; (4) more or less complete disappearance of fat from the cells of fatty tissues; (5) albuminous and fatty degenerations of glandular epithelium, specially well marked in the liver; (6) degeneration of nerve tissues, most marked in the nerve-cells of the cerebral cortex and the spinal cord. The terminal nerves seemed also to be affected in a few cases but he was not certain whether the changes were attributable to arsenic or to some other causes. Sometimes there was over production of cutaneous epithelium and of fibrous tissues in some of the organs which were also the seat of degenerative processes. With regard to the latter change it was generally difficult to exclude the possible influence of other causes. The post-mortem examinations which he had made of the rats used in the experiments which had been previously related had yielded very similar results. In fact, with one exception, the changes observed in the various organs and tissues had been identical with those found in the human subject, but with regard to pigmentation he had obtained no result. He expected this difference, for all his experimental rats were albino rats; the absence of pigmentation in these cases was an additional confirmation of the theory which he had formulated many years ago regarding the origin of melanin. At the time when he started his experiments he tried to obtain some tame grey rats, but he was not able to get any. It would have been impossible to conduct carefully systematic experiments with wild rats. A detailed account of these pathological investigations was not yet ready and would not in its present state add materially to the value of the evidence which he had already obtained. There remained in his mind no doubts regarding the similarity between the lesions observed in the bodies of patients who had died from the effects of arsenical beer and the lesions observed in the carcasses of rats to which solutions of arsenious acid in water or in beer had been given over periods varying from 30 days to 90 days. Several of these cases had not taken proportionately more arsenious acid than the human victim. The mode of death in both cases was usually sudden, as if due to cardiac failure or failure of the respiratory muscles. It was also noticeable that when small quantities of arsenic were given a fatal result did not usually occur before the end of three months and that recovery was possible at the end of that time. The experiments on rats had also the object of determining whether arsenious acid in beer was more poisonous than arsenious acid dissolved in water. The changes of weight observed in animals taking equal amounts of arsenious acid dissolved in beer or in water had already shown that arsenious acid dissolved in water seemed to be more injurious than arsenious acid dissolved in beer; the post-mortem examination confirmed this view, for the degenerative changes were most marked in rats taking watery solutions of arsenious acid. Alcohol up to the amount usually present in beer did not seem to affect the rats unfavourably but the addition of alcohol up to 10 per cent. of the total fluid seemed to have a detrimental effect. The bad effects [illegible]tained with strong solutions of alcohol even in moderate quantities [illegible]ated that dilution had an important influence upon [illegible] of the [illegible] gard to the possible presence of amines in arsenical beer cacody[illegible] able pow[illegible] to him to be among the most noxious amines which could reasonably be expected to be present in beer; the results obt the only case in which cacodylate of sodium was administered much in accordance with what was known before of the physi action of this salt that he did not think it necessary to m experiments. Far from having a detrimental effect during period parable to those of the Salford epidemic, cacodylate of sodium s to have a beneficial effect even when administered in large doses animal treated with cacodylate of sodium bore better the effects diet than a control animal taking no arsenic at all. Anoth receiving as much arsenic, in the form of arsenious acid, cacodylate rat became, on the contrary, seriously ill under the collateral experimental conditions. The post-mortem state of agreed with the symptoms during life. In the rat receiving ar acid, and which died in consequence, the usual degenerative c were observed and the fat of the fatty tissues had disappeared e from the parts where it was usually found. The cacodylate rat, contrary, was apparently quite well when killed, its organs normal appearance, and there was the usual amount of fat u [illegible]en and in other situations.

[illegible] the whole case Professor Delépine presented the following [illegible]—viz.: 1. The 1900–1901 outbreak was due to the pres arsenious acid in the beer drunk by the victims. 2. The pres an amount of arsenious acid capable of producing such an o could only be accounted for by the use of arsenical glucose o sugar as malt substitutes. 3. The presence of smaller quant arsenious acid such as might be due to the use of badly prepare though seldom dangerous to the same extent, was capable of pr injurious effects in ill fed or weak individuals. 4. Bad feedi other deteriorating influences were sufficient to account for the incidence of cases of poisoning among classes of people liable t influences.

The Commission then adjourned.

lower end of the colon and one in the rectum. These ulcers had resulted from a destruction of the glandular layer of the mucous membrane, the muscularis mucosæ not being affected. Diplococcus pneumoniæ was isolated from the blood and from the pneumonic portions of lung, and in sections through the ulcers in the colon there could be seen diplococci which stained by Gram's method

With regard to other mucous membranes pneumococcic lesions of practically every such surface have been described and verified bacteriologically

In addition to causing acute abscess of the tonsil diplococcus pneumoniæ appears to be a fairly frequent cause of acute membranous tonsillitis and pharyngitis. The exact bacteriological identification in these cases is rendered difficult by the fact that the organism is a frequent parasite of the healthy mouth. But the number of cases in which there are the formation of a false membrane and destruction of the superficial layer of the epithelial membrane associated with the presence of the coccus in predominant numbers, and without any of the other bacteria—bacillus diphtheriæ, streptococcus pyogenes, and saccharomyces albicans—which are known to cause similar lesions, leaves little doubt as to the fairly frequent occurrence of an acute membranous pharyngitis due to this cause. Bezançon and Griffon, who have especially studied this class of cases, have tested the serum reaction in 10 cases of acute non-diphtheritic pharyngitis.[6] Employing the method which they have devised for testing the serum reaction in pneumococcic infection, these writers claim to have obtained a positive agglutinative reaction with cultures of diplococcus pneumoniæ in every case [7]

Amongst the consequences of pneumococcic pharyngitis is perforation of the pillars of the fauces, as in a case recorded by Munro.[8] In this case there was a membranous tonsillitis which spread over the palate from one side to the other, and diplococcus pneumoniæ was present in six out of seven examinations made. During the case some nerve symptoms were observed which were thought to be suggestive of diphtheria, but which were probably an example of the paralysis which has been observed on a few occasions as a sequela of pneumococcic infection

Another possible result of pneumococcic pharyngeal infection, spreading along the Eustachian tube, is the otitis media which is not infrequently caused by this organism

I have also examined a single case of laryngitis probably due to this organism and occurring in a man who died with a pneumococcic abscess of the lung On one of the false vocal cords there was a greyish membrane which was closely adherent to the underlying surface. Diplococcus pneumoniæ was isolated in pure culture from the pulmonary lesion, and diplococci resembling it were seen in smear preparations made from the laryngeal membrane.

In connexion with the eye there is a form of membranous conjunctivitis caused by the coccus, sometimes occurring without any obvious source of auto-infection, sometimes in the course of a pneumonia, and then probably caused by direct conveyance of infection This membranous pneumococcic conjunctivitis is probably not so common as a more localised suppurative keratitis due to the same cause which has been described by several writers Uhthoff, for instance, out of 50 cases of suppurative keratitis found diplococcus pneumoniæ in pure culture 24 times and associated with other bacteria seven times.

Diplococcus pneumoniæ does not seem to have been often found by those who have specially studied the bacteriology of the uterus and vagina, whether healthy or diseased. Doyen states that he has identified the coccus in the secretion of the healthy vagina but I cannot find any record of its occurrence in cases of vaginitis Cohn[9] has recorded a case of pneumococcic endometritis and general infection in a woman, aged 35 years, who was admitted into hospital with metrostaxis coming on three months after a miscarriage. After death there were found suppurative endometritis with retained portions of placenta, ulcerative endocarditis affecting the aortic valves, suppurative meningitis, and two softening infarcts in the spleen Diplococcus pneumoniæ was present in all the lesions.

With regard to pneumococcic salpingitis there is rather more evidence; Witte identified the coccus in four out of 39 cases examined, Hartman and Morax found it in two out of 33 cases, and other cases have been published.

Infection by the vagina has been thought to explain the sex-incidence of pneumococcic peritonitis, but as a matter of fact the significance of available statistics on this point is not quite clear It is true that a large majority of the cases recorded in children have happened in girls, but on the other hand the few cases which I have been able to find recorded in adults, and occurring otherwise than as an incident of a general infection, have all been in males.

The last case of pneumococcic infection of the mucous membranes which need be mentioned is the rather remarkable one published by Cary and Lyons[10] of a boy, aged 11 years, who, with an attack of acute lobar pneumonia, developed on all the mucous surfaces of the body open to inspection a pseudo-membranous exudation caused by diplococcus pneumoniæ. The boy's illness began on Jan 5th with sore-throat and pyrexia. On the 7th there were indications of lobar pneumonia and an abundant white exudation membrane was noticed on the tonsils. This exudation membrane spread to the general cavity of the mouth and to the gums it could be peeled off in shreds, leaving beneath a raw, granular, bleeding surface. Four days later a fibrinous conjunctivitis with numerous subconjunctival hæmorrhages developed Two days later again the glans penis—the organ had been circumcised—became covered by a thick, adherent membrane. On the day next following mucus was found in considerable quantities in the stools and a deposit of false membrane formed round the anus. The patient ultimately recovered Diplococcus pneumoniæ was present in the sputum and was identified in all the various exudation membranes, pure cultures were isolated and tested on rabbits in the usual way

A consideration of these manifestations of pneumococcic infection in mucous membranes generally shows that here the pathogenic action of the coccus, after allowing for different local conditions, may be much the same as when it causes a lobar pneumonia. There are the same fibrinous exudation and destruction of surface structure and the same tendency to extravasation of blood that are seen when the pulmonary vesicles are attacked.

Sutton

THE TREATMENT OF GONORRHŒA, WITH SPECIAL REFERENCE TO BLADDER IRRIGATION[1]

BY F SWINFORD EDWARDS, F R C S ENG,
SURGEON TO THE WEST LONDON HOSPITAL, TO ST PETER'S HOSPITAL FOR STONE AND GENITO-URINARY DISEASES AND TO ST MARK'S HOSPITAL FOR FISTULA AND OTHER DISEASES OF THE RECTUM

AS the outcome of recent bacteriological investigations I think we shall all be agreed that gonorrhœal urethritis is a localised septic infection, in some cases becoming even general owing to the presence of a micro-organism which goes by the name of "gonococcus" and which was first demonstrated in 1878 and 1879 by Bouchard and Neisser This organism is kidney shaped and is met with as a diplococcus invading epithelial and pus cells or lying free in the secretion. Form alone does not distinguish the gonococcus from cocci which are found, according to Lustgarten and others, in the normal urethra, the distinction between them being that whereas they both stain with the aniline dyes the gonococcus does not stain with Gram's solution as does the other Other micro-organisms are found at times in conjunction with the gonococcus—viz, the bacillus tuberculosis, the staphylococcus, and the streptococcus the presence of which may account for suppuration in distant parts, as in suppurative gonorrhœal arthritis. In order therefore to cure a gonorrhœa one must direct one's energies to destroying these micro-organisms or to rendering the tissues attacked an unfit habitat for them

The course run by a gonorrhœa may be divided into four periods (1) the period of incubation, (2) the acute stage;

(3) the subacute stage; and (4) the chronic stage, known generally as gleet. The treatment for one and all of these stages may be divided into general and local. The following constitutional treatment is of use in the first three stages—viz., rest from all active exercise and sexual excitement; abstinence from alcohol, coffee, spices, and salt food, and possibly from tobacco; the free administration of diluents, a daily saline purge, and a hot sitz bath night and morning if obtainable. Sandalwood oil in doses of from 20 to 30 minims three times a day preferably in the capsule form may be given combined with an alkaline and sedative draught, such as bicarbonate of soda and belladonna or of solution of potash, hyoscyamus, and buchu. Here let me remark that I consider local treatment far more important in the treatment of this, which is, at all events at first, a local disease, than the administration of medicines by the mouth. I am well aware that many cases of urethritis get well without local treatment, but I doubt if a true gonorrhœa does so, excepting after a long and weary course.

Let us now consider the local treatment to be adopted in the first or incubation period—i.e., before suppuration becomes established—which usually lasts about three days, though this stage may be curtailed or considerably lengthened. Should the medical attendant be fortunate enough to see the case within a day or two of contagion and when only a certain degree of heat and irritation are complained of, together with some meatal redness and mucoid discharge, I think he is justified in endeavouring to cut short the attack either by the application of a caustic solution or by the injection of some strong antiseptic, as, for example, a solution of perchloride of mercury (1 in 2000), a 2 per cent. solution of mercurol (a new preparation recently introduced by Messrs. Parke, Davis, and Co. and which is a chemical compound of nucleinic acid with mercury), or a solution of nitrate of silver (five grains to the ounce), to be repeated in weaker strengths if necessary. The patient should be directed to urinate immediately before the injection, a point highly necessary to insist upon at any period of the disease when treatment by injections or irrigations is being carried on. Strong solutions of nitrate of silver—as, for instance, from 10 to 20 grains to the ounce—may be applied to the anterior urethra through a urethroscopic tube by means of a cotton-wool swab. This application, as well as strong injections, may be made painlessly if the urethra is first rendered anæsthetic by the injection of cocaine or eucaine. I am now in the habit of using a 4 per cent. solution of each in combination. These caustic and antiseptic applications may be changed for astringents in two or three days if the irritation is diminishing. General treatment on the lines already given should run concurrently. Another method of much service for the rapid cure of what is evidently a commencing gonorrhœa is urethral irrigation by means of which the canal is flushed out from behind forwards with half a pint of some weak antiseptic wash, such as borax, boric acid, or permanganate of potassium repeated every two or three hours. For this treatment to be properly carried out confinement to bed or room is necessary and irrigation should be continued, though less frequently, through the night. By either of these methods a week or 10 days will probably suffice to put an end to all trouble

For the second or acute stage I think most medical men are still of opinion that treatment should be chiefly general. With a view to render the urine non-irritating large quantities of fluid should be taken such as hot water, milk-and-soda-water, barley-water, and weak tea. One or other of the following mineral waters is usually beneficial—viz., Contrexéville, Wildungen, Vichy, and Kronenquelle. The patient should be encouraged to micturate frequently, even rising at night for the purpose. Where copaiba, cubebs, and santal oil disagree methylene blue, urotropine, or salol may be substituted. Hot sitz baths at this stage are of the greatest comfort. Complications such as retention of urine and chordee may require the attention of the practitioner.

After the lapse of about a fortnight or possibly longer the acute stage will have subsided, as shown by the diminution of scalding and the alteration in the character of the discharge which will have become thinner and more muco-purulent. When all pain on micturition has ceased local treatment may be commenced in the form of injections, retro-jections, and irrigations. In the majority of cases urethral injections as carried out by the well-known small glass syringe will suffice, provided, of course, that the inflammation has not extended beyond its reach—viz., into the membrano-prostatic urethra. When it is limited to the anterior urethra any of the following may be used with advantage: sulphate of zinc (one grain to the ounce), permanganate of zinc (one-eighth of a grain to the ounce), liquid extract of Canadian pine (one drachm to one ounce), nitrate of silver (quarter of a grain to one ounce), and either of the more recent preparations—viz., protargol (1 to 2 per cent.) or mercurol ($\frac{1}{2}$ to 2 per cent.). Of these I have recently been trying the latter and, I may say, with marked success. Where the deep urethra is involved, as shown by the "wash-out" test, I know of nothing to equal irrigation of the bladder and urethra as advocated and carried out by Janet and Valentine. By this method, if employed night and morning, the patient is usually well in a fortnight or three weeks, possibly sooner—that is, provided that no complication exists. The apparatus consists of a glass reservoir, holding at least a pint, provided with six feet of rubber tubing, stop-cock, and glass nozzle. The reservoir is hung about five feet above a couch on which the patient lies and it is filled with a hot solution of permanganate of potassium, commencing with a strength of 1 in 6000. The patient having just emptied his bladder, the glass nozzle is loosely inserted into the meatus and the stop-cock is partially turned on, or if a clip is used this is but slightly compressed. In this way the anterior urethra is first thoroughly flushed out. By pressing the nozzle firmly into the urethra and at the same time allowing a fuller current to pass, the fluid after distending the anterior urethra will flow on into the bladder. At first it may be difficult to overcome the resistance of the compressor urethræ muscle, but with patience and a little manœuvring this will be accomplished. When the bladder is full the stream is arrested and the nozzle is removed and the patient assumes the erect posture and expels the fluid by natural efforts, somewhat compressing the distal end of the urethra with his finger and thumb in order to increase the back-pressure. Other drugs may in this way be used as, for instance, mercurol or protargol with a strength of 1 in 400 to commence with.

In chronic gonorrhœa or gleet, whether shown by a sealing of the meatus, a slight discharge of muco-pus often only seen on rising from bed, or by shreds in the urine, a thorough examination should be made with the inflating urethroscope as supplied by Schall. Although aerial distension modifies the appearance of the flaccid urethra it certainly facilitates the discovery of lesions such as stricture, inflamed follicles, granular patches, adventitious pouches or pockets, and papillomata, and through its tube one can successfully treat the majority of these. There are those who claim to find it to be equally useful in the deep urethra, but this is not my experience, for the mucous membrane as seen through it in this part of the urethra always appears to me to be swollen and congested owing, no doubt, to the pressure of the tube, and inflation is here impossible. Although it is possible to see the vera montanum it is difficult to tell whether the appearance seen is due to disease or to the method of examination. When a gleet has lasted for six months, especially if there have been previous attacks, the urethra should be examined for stricture, even although the patient assures you that his "stream of urine is as good as ever." For this purpose the exploring bougies of Otis are excellent. Should a stricture be found a urethroscopic examination may be unnecessary and treatment directed to the cure of the stricture should be undertaken forthwith. You will note the word "cure," for contrary to the old dictum, "once a stricture always a stricture," I hold the opinion that many cases permit of a permanent cure if thoroughly and intelligently treated. But I must refrain from all temptation to go into the subject of the treatment of stricture, however alluring, on the present occasion.

Granular patches of congested areas of considerable frequency in long-standing cases are met with chiefly in the bulbous urethra and can be satisfactorily treated by the application of nitrate of silver on a wool swab which may also suffice for the cure of inflamed follicular openings. Warty growths should be curetted and small follicular abscesses, whether of Littré's glands or those of Cowper, may be treated either by electrolytic puncture or intra-urethral incision. These several manipulations when carried on through a tube from five to six inches in length, the lumen of which does not measure more than a No. 10 or No. 12 English catheter, require care, patience, and considerable dexterity.

Just as the acute phase of gonorrhœa is not limited to the penile urethra but may extend backwards, involving in turn the membranous and prostatic urethra the bladder, even extending up to the kidneys with fatal results, so a gleet may have its seat in the deep urethra in the prostatic ducts, and seminal vesicles For chronic posterior urethritis the following methods suggest themselves—the passage of large-sized steel sounds, possibly coated with some tenacious ointment, electrolysis, Janet's irrigation, instillation of some silver salt, or even the application of lunar caustic itself Personally I have come to rely entirely upon either irrigation or instillation, or the one supplemented by the other For chronic prostatitis or vesiculitis where muco-pus is pent up to be discharged at intervals I know of nothing to touch massage carried out by a finger in the rectum Although somewhat uncomfortable for both patient and surgeon it is wonderful how soon the urine clears up which had previously been loaded with shreds and threads.

Until quite recently long standing cases of gonorrhœa and gleet were amongst the most difficult a surgeon was called upon to treat, but now owing to the introduction of Janet's irrigation treatment in uncomplicated cases a cure may be confidently expected within a few weeks

I have abstained from inserting notes of cases illustrating many of the methods of treatment in this communication, also from touching upon the disease as found in the female and upon the many complications in the male, for time will not allow of it Let me conclude by asking the following questions, to each of which I will append a short answer, rather by way of inviting discussion than with the object of closing it

1. Is it necessary to distinguish between gonorrhœa and a simple urethritis?—If it is it necessarily follows that it should be a routine practice to examine microscopically every case of urethral discharge at all events at its onset But I very much doubt if one medical man in 50 does this or if he does, it is not with the object of directing treatment but rather with a view of determining a social or medico-legal question

2. Are we warranted in trying to abort an attack?—I most certainly think that we are if we see the case before the acute stage and if the patient will consent to lie up for about a week

3. Is treatment by bladder and urethral irrigation to be recommended in the acute stage?—Janet and Valentine both favour it and Dalton,[2] speaking of the acute stage, says "*Local treatment has always been a much debated point*, many authors advocating waiting for the acute stage to pass off before any local treatment. This waiting certainly allows the gonococci to increase and to invade the tissues more deeply and since irrigation has become an actual treatment it seems more rational to endeavour to arrest the morbid process as soon as possible." Irrigation having been decided upon the earlier it is begun the better Patients who are seen very early in this disease will pass *through it without practically* any pain and those who are further advanced and in the stage of profuse discharge, ardor urinæ, &c., will quickly be reduced to a comfortable state. It is not at all unusual for these cases to be completely well in three weeks. Neisser,[3] speaking of the treatment of acute gonorrhœa, says "Our procedure is as follows (i) determination of the presence of gonococci &c., (ii.) in all cases the immediate commencement of injections" From what I have said it will be gathered that I do not advise injections in the acute stage. I have refrained, *as a rule*, from all interference with the urethra, believing that any abrasion of the urethral mucous membrane might open the way to a general septic infection. I have also hesitated to use Janet's irrigation in a profuse urethral discharge, such as exists when the disease is at its height, fearing that I might not be able sufficiently to disinfect the urethra to obviate all risk of setting up a gonorrhœal cystitis. I shall be glad to be convinced that I need not be *so timorous*.

4. My fourth question is What constitutes a cure?—We must not conclude that a patient is cured when he no longer sees any discharge, not even the morning drop, for shreds may still remain in the urine, the heavier variety of which—viz., those which sink to the bottom of the glass—usually contain gonococci, not so, however, the fine partially transparent filamentous threads which float in the urine. For my part, I look upon a patient as being cured when, a month after all treatment has ceased and he has reverted to his ordinary course of life, no sign of discharge is present there is no sealing of the meatus, and no débris in the urine

Harley-street W

AN ANALYSIS OF A SERIES OF OPERATIONS FOR THE EXTRACTION OF CATARACT

BY R H ELLIOT, M B, B S LOND, F R C S ENG,
CAPTAIN I M S; ACTING SUPERINTENDENT OF THE GOVERNMENT OPHTHALMIC HOSPITAL, MADRAS

THIS series of cases—77 in all—embraces a period from January, 1897, to April, 1901 The cases are consecutive and all lenses removed by me during the period are included Any case was submitted to operation in which there was a reasonable prospect of improving the vision One patient was a European, three patients (embracing four eyes) were well to-do natives, and the rest were pauper natives. The cases are grouped together in the first place because they include all the extractions of the lens performed by me in the interval between the two periods in which I have acted as superintendent of the Government Ophthalmic Hospital, Madras, and, secondly, because a careful study of the series has led me for the present to abandon the simple operation in favour of the combined method The latter reason supplies my apology for intruding such a small series on public notice.

The operation adopted consisted in, first, preliminary capsule rupture with Bowman's needle, secondly, a sclero-corneal incision, varying in size from nearly a half to a quarter of the circumference, according to the size of the nucleus to be dealt with, thirdly, expression of the lens, and the clearing of the chamber with a curette and cotton wool sponges mounted on little sticks, and fourthly, the application of an antiseptic dressing Iridectomy was not performed as a routine measure. All instruments were boiled and a general antiseptic regimen was adopted

The total number of eyes operated on in the series was 77, of these, 39 were right eyes and 38 were left eyes The total number of patients represented was 53, of these 25 were men and 28 were women Of the 53, 40 were caste Hindus, 4 were Mahomedans, 8 were Hindus without caste, including native Christians, and 1 was a European Their ages were as follows 1 was 29 years of age, 7 were between 30 and 40 years, 18 between 41 and 50 years 15 between 51 and 60 years, 7 between 61 and 70 years, 4 between 71 and 80 years, and 1 was 90 years of age

Of the 77 cataracts extracted 18 were Morgagnian, 38 were cortico-nuclear, and 21 were *nuclear The large relative* preponderance of Morgagnian cataracts is due to the fact that the first 39 operations of the series were done in an up country station, in which no cataract-extractions had been performed for many years, many of the cataracts were therefore hypermature, out of these 39 no less than 13 were Morgagnian—i.e. 33 3 per cent

COMPLICATIONS PRESENT BEFORE OPERATION

Catarrhal ophthalmia—This complication which occurred in 12 *cases was always dealt with before operation and* led to no serious consequences in any case.

Granular ophthalmia with slight pannus—This condition occurred twice in the same patient. In spite of long-continued treatment beforehand there was considerable ciliary trouble in both eyes after operation.

A corneal nebula was present in one case

Pterygium—There was pterygium in six cases Transplantation *was only* performed once the growth being avoided by making an oblique section in the other cases

Immaturity of cataract—*Five cases* presented this condition

Tension + 1—This was noted in one case. A free prolapse of the iris occurred during the after treatment. After iridectomy the case progressed evenly and had four metre[1] vision

---

[2] Edinburgh Medical Journal, July 1901

[3] Dermatologisches Centralblatt, vol i, No 1

[1] Four five- six, &c. metre vision implies the ability to count miniature bull's-eyes correctly at these distances A vision of M B.E (miniature bull's-eyes) at six metres is equivalent to $\frac{6}{6}$ vision by types

Chamber very shallow.—In two cases this was observed. The iris was scraped during section by a knife. Both patients did well and had good vision.

Complete posterior synechia.—There was complete posterior synechia in one case. Delivery was effected by the vectis after free iridectomy. There were free hæmorrhage from the iris and a slight escape of vitreous. Vision was raised from a mere perception of light and darkness to the ability to detect hand-movements at a distance of three metres.

Dislocation of the lens into the hyaloid.—This occurred in two cases. In both the lenses had been couched by Mahomedan operators. In one the dislocation was of some months' standing and a Morgagnian nucleus was removed by the vectis, the capsule being dragged out by forceps. There was a slight escape of vitreous and the case did well, four-metre vision being secured. The second case had been couched the day before my operation. There were marked ciliary congestion, intense pain, and tension was + 2. Under chloroform a Morgagnian nucleus was delivered by the vectis, with very slight escape of vitreous. Some ciliary congestion continued. Recovery with six-metre vision followed.

Great age of the patient.—One case was complicated by the advanced age (90 years) of the patient. Her skin hung in satiny folds and she looked more like a monkey than a woman, but she made an excellent recovery. The night after her operation she got out of bed and stole a necklace belonging to another patient. She counted miniature bull's eyes at four metres and could have done better but would not continue the test.

A COMPARISON OF THE SIMPLE AND COMBINED (I.E., WITH IRIDECTOMY) OPERATIONS.

Of the 77 extractions, 52 were conducted by the simple method, 24 by the combined method, and one had undergone preliminary iridectomy four years before.

Of the 52 simple cases a threatened prolapse was successfully treated by the use of eserine in 1 case, or 1.92 per cent.; a slight prolapse not demanding iridectomy occurred in 3 cases, or 5.76 per cent.; a prolapse of the iris demanding excision by the severity of the symptoms excited occurred in 7 cases, or 13.46 per cent.; and the eye made an uninterrupted recovery in 41, or 78 84 per cent. of the cases.

The average vision was as follows: (1) in the simple cases in which no prolapse occurred it was M.B.E at 5·02 metres (N.B. This calculation excludes two eyes of one case in which there was cupping of the disc before operation, it also excludes six cases in which the vision was good but not tested, and it includes one case in which eserine reduced a threatening prolapse); (2) in the simple cases in which a prolapse was excised as soon as it was recognised it was M.B.E. at 5·20 metres; (3) in the simple cases in which iridectomy was not performed, though a prolapse had occurred, it was M.B.E. at 2 5 metres; and (4) in the combined cases in which iridectomy was performed at the time of operation it was 4·94 metres (N.B. This calculation excludes four cases with good vision which escaped testing; it also excludes two cases of escape of the vitreous, one injury inflicted during convalescence, one case of old fundus change, and one of complete posterior synechia) If the last two cases alone are excluded the average vision in this group falls to 4·31 metres.

In considering the above statistics, it is to be remembered that the group of simple cases in which operation for prolapse was performed was a comparatively small one and by good fortune no accident occurred in any of the late iridectomies. An experience of 1100 cataract operations already published in the *Indian Medical Gazette* of 1897 convinces me that it would be very unsafe to presume on these figures. I regard prolapse demanding late iridectomy as the gravest complication that can arise in the after-treatment of a cataract case, suppuration being, of course, excepted. The high ratio of visual result here shown may, however, be safely regarded as an indication that the performance of an iridectomy does not materially lower visual acuity in eyes submitted to cataract extraction.

The lower visual results in the cases of combined extraction—i.e., in those in which iridectomy was done at the original operation—are easily explained when we remember that in this series an iridectomy was in a good many cases made at the time of operation because the case was complicated. The simple cases thus represent a more favourable class than do the others.

In order to establish a comparison between the two classes, a number of patients were selected in whom the apparently the same in both eyes before operation and had double cataract. The results of this series ments are as follows:—

Number of case.	Kind of operation.	Side.	V = M.B.E. at—
1	Simple.	Right.	6 metres.

	Combined ‡	Left.	3

---

* The delay of one week in testing the right eye accounts for t difference fully.

† The left eye was injured by a bedpost on the twenty-first day severe hæmorrhage followed and a good deal of ciliary irritation was excited.

‡ There was a slight escape of vitreous from the right eye d operation.

While freely admitting that the test applied was inferio in delicacy to that which would have been used in dealing with the more intelligent and appreciative European and that this detracts somewhat from the value of the results, nevertheless the facts are sufficiently consistent and have been sufficiently accurately obtained to warrant the deduction that in these cases the simple operation gave no better results than did the combined operation. I have been led to the same conclusion by the consideration of other series of operations which I have had the opportunity of performing.

In favour of the simple operation it is usually advanced (1) that it gives better visual results than does the combined operation; (2) that it provides a more active pupil than does the combined operation; (3) that the dazzling caused by the presence of the coloboma is avoided; and (4) that there is less mutilation of the eye. With the first contention I cannot agree; as to the second, I find that the pupil in a well-performed case of the combined operation is very active and I doubt if there is anything in favour of this proposition; as to the third, the upper lid covers the coloboma and the patients do not seem to be aware of its presence; and as to the fourth, it appears to me to appeal to a sentiment which is not founded on sound surgical principles. I believe, in common with many other surgeons, that the after-course of the combined operation cases is more even and uneventful than is that of the simple operation.

Against the simple operation there is always the grave danger of prolapse of the iris. Even Knapp admits to the occurrence of prolapse in 7 6 per cent. of his latest cases; most operators admit more, and I believe that the 14 per cent. met with by me in this series is not excessive. It may be argued that the cases now under review furnish no argument against the simple operation, since the standard of vision in those in which a prolapse was excised is so high. A wider experience than this series affords has convinced me that the danger of losing eyes after prolapse is a very real one, and the anxiety for the three or four days after operation is too dear a price to pay, except for solid advantages which I fail to see that the simple operation can afford. I take the liberty to quote an extract from a paper on Cataract which I wrote and which was published in the *Indian Medical Gazette* in 1897.

> On reviewing the statistics of 1068 consecutive cases of cataract extraction performed by the writer in hospital practice, this statement is strongly illustrated. In 409 cases an iridectomy was performed at the time and the records show that 7·5 per cent. of these cases failed. In 659 cases the simple operation was performed and 8 5 per cent failed. If, however, we separate those cases of simple extraction in which a prolapse of the iris complicated the subsequent course of treatment

from the cases not so complicated, the former show 20·3 per cent. of failure, while the latter show only 6 per cent. It is therefore obvious that in the series under review the less favourable aspect of the cases of simple extraction is due to the frequency of occurrence of this dangerous complication.

Working now with increased experience and improved methods I think that I could greatly better these results, but even so my appreciation of the danger does not lessen. The operation may be done most skilfully, the iris may be left well reposed in its natural position, the incision may have been the limited one required for the removal of a small Morgagnian nucleus and may lie exactly in the sclero-corneal margin or even in front of it, and yet the sudden bursting of the section and the escape of a rush of fluid which has been dammed up behind the iris may carry the upper portion of that membrane into the wound and lead to the serious train of symptoms which warn us that prolapse is present. Neither eserine nor atropine avails to prevent the accident. Iridectomy must now frequently be performed under very disadvantageous circumstances; if an anæsthetic is given the eyeball rotates upwards and the effort to pull it down by means of the forceps threatens the integrity of the hyaloid membrane and with it the safety of the eye; again, if we rely on cocaine alone the strangled iris is so hyperæsthetic that the patient finds it hard to keep quiet and his sudden spasmodic movements make the operation one of the gravest anxiety.

Of the 24 cases operated on by the combined method iridectomy was performed nine times in order to deliver a lens which would not present otherwise; twice in order to facilitate the clearing the chamber of cortex; once on account of total posterior synechia; five times involuntarily by the knife in section; and seven times for miscellaneous reasons. In cases of double cataract in which the first eye was operated on by the combined method whether accidentally or on purpose the second was when possible reserved for a simple operation for purposes of comparison.

COMPLICATIONS DURING EXTRACTION.

In addition to the complications already mentioned above the following were met with during extraction:

The patient so troublesome that chloroform was given.—This was the case three times. I should now inject morphia hypodermically instead of giving chloroform. It has an excellent effect in quieting the patient and at the same time does not deprive us of his help in turning the eye downwards

Free hæmorrhage from the cut iris.—This occurred twice It did not affect the prognosis in either case.

The capsule removed by forceps.—This had to be carried out in two cases.

Escape of vitreous.—This took place 11 times. The escape was slight in five cases (vision respectively = M.B.E. at 6, 1·5, 6, and 2 5 metres, and hand-movements at 3 metres); moderate in one case (vision was good but untested, as patient absconded); and extensive in two cases (vision = counting fingers at 1 metre and at 6 metres respectively).

The nucleus very small—This was the condition twice in the same case. The patient was a *guru*[2] of great sanctity and had been blind for 17 years. Tension in both eyes was above normal, though not markedly so. He was led in by two of his friends. On needling the first cataract there was a free escape of milky fluid but no nucleus could be found; at first it was feared that it had sunk back into the vitreous, but this was not the case and so on needling the second cataract the nucleus was most carefully looked for; after the section the escaping fluid was found to contain a tiny nucleus of the size of a small cocaine lamella (such as one uses for eye medication). The patient was able after operation to count fingers at six metres with both eyes and to find his way about alone with ease; he had cupping of both discs. The effect in the district was to bring in a number of cases as this man's reputation was widespread.

COMPLICATIONS DURING THE AFTER-TREATMENT.

Hæmorrhage into the anterior chamber.—This occurred in four cases. In one case it was due to a fit of coughing on the fifth day; in two cases it was due to injury by striking the eye against furniture on the fifth and twenty-first days respectively; and in one case it was brought about probably by rubbing the eye on the fifth day. Vision was good in all eventually (M B.E. at 6 metres in three cases and at 1 5 metres in one case).

Section burst by rubbing—In four cases this happened—in one case on the third day, in one on the seventh day, and in two on the tenth day. In the last two cases the rupture of the section was attended by severe pain and obstinate vomiting. All four patients obtained good vision (M.B.E. at 6, 3, 3, and 4·5 metres respectively).

Section leaking.—This was present in seven cases—till the fourth day in two cases, and till the fifth, sixth, seventh, and eighth days in the others. Of these patients three were between 50 and 60 years of age, one was 65 years of age, and three were over the age of 70 years. The vision was good in all (M.B.E. respectively at 1·5, 2, 3·5, 4, 5, and 6 metres; good but untested in one case).

Keratitis and ulceration of the cornea.—These complicating conditions were present in four cases. In three cases the keratitis was of the striped variety and it cleared up leaving good vision (M.B E. at 4 metres in one case and at 6 metres in two cases); one patient was a *ganga*-smoker and he and one other of the patients repeatedly took off their bandages. In the fourth case too much cocaine was used and ulceration followed; this was aggravated by the patient leaving hospital surreptitiously for four days. He eventually recovered vision (M.B.E. at 1 metre).

Cyclitis (subacute).—This occurred in three cases. In one case total synechia had existed and the lens was removed by the vectis. In the two eyes of one patient there had been precedent granular ophthalmia and pannus. One patient got good vision while the other two patients derived indifferent vision (hand movements at 3 metres, M.B.E. at 6 metres and fingers at 6 metres respectively.)

Secondary cataract.—There was secondary cataract in three cases. The cataracts were needled on the twentieth, twenty-third, and twenty-seventh days respectively (vision at 3 5, 6, and 5 metres respectively).

Prolapse of the iris.—This condition has already been dealt with.

The vision of the patients was tested after operation by ascertaining at what distance they could count miniature bull's-eyes. These consist of black dots on a white ground, which are shown to the subject through an aperture in a piece of cardboard. The examiner can thus show as many or as few as he wishes. I find by experiment that the dots can be counted by a normal eye at 10 metres. Recruits for the native army are required to count correctly these bull's-eyes at six metres. Patients were tested up to six metres and not beyond The test is that in use in the Madras Eye Hospital. It is a convenient one when dealing with patients whose intelligence and education are both of a very low order Several patients absconded rather than submit to being tested; several left without warning as soon as they found that they were in possession of good sight. The native women especially object to wearing glasses and one often hears them saying: "What do I want with glasses? The other women will laugh at me; I can see quite well enough." Some were tested for near vision but the number of cases so tested is, unfortunately, too small to be worth recording. The symbols M.B.E. with the distances in metres in this paper mean that the patients could count miniature bull's eyes at the distance in metres signified by the number affixed.

An effort was made to keep the patients as long under treatment and observation as possible, and with this end in view the date of supply of glasses was delayed till the patients would stop no longer. The improvement in vision from week to week was very marked in many cases. The following table shows the time during which the cases were under observation before final testing:—

One week	1 case.
From two to four weeks	23 cases.
,, one to two months	39 ,,
Over two months	7 ,,
Time not recorded	7 ,,
Total	77 cases.

The following is an analysis of the visual results obtained[3]:—

Counted miniature bull's-eyes	at from 1 to 1·5 metres ...	4 cases.
,, ,,	at from 2 to 2·5 ,, ...	4 ,,
,, ,,	at from 3 to 3·5 ,, ...	6 ,,
,, ,,	at from 4 to 4·5 ,, ...	7 ,,
,, ,,	at from 5 to 5·5 ,, ...	6 ,,
,, ,,	at from 6 metres and above	34 ,,
Vision good but untested		10 ,,
Counted fingers at 6 metres		3 ,,
,, 2 metres		1 case.
Could distinguish hand movements at 3 metres		1 ,,
No improvement after operation		1 ,,
Total		77 cases.

---

[2] Guru = a holy man.

[3] A vision of M.B.E. at one metre may be counted as one-tenth normal vision.

The 61 cases with vision of M.B.E. at from one metre to six metres may be unhesitatingly classed as successes, as before operation 58 of these patients were quite unable to count fingers in any light, and were only able to recognise the movements of a hand in front of the eye, as "a shadow moving"; the three others counted fingers respectively at three inches (final vision M.B.E. at five metres), at three feet (final vision M.B.E. at six metres), and at three feet (final vision M.B.E. at six metres, and $\frac{6}{12}$ths by types in a European).

Of the 10 patients with good vision but untested by the bull's-eyes, all could readily count fingers without a glass and all the cases were undoubted successes. These patients absconded because they were satisfied with the result and did not want to be kept further under observation. Six of them were a month or less under treatment; the rest were treated for longer periods. Two of them counted fingers at one foot before operation; the remaining eight patients were only able to distinguish the shadow of the hand moving in front of the eye.

To the remaining six cases the following remarks apply. 1. Two eyes in one patient were raised from faint perception of light to ability to count fingers at six metres. There were very opaque Morgagnian cataracts, with a history of 17 years' blindness and cupping of both discs. The double result was probably the most brilliant of the whole series and, as has been said already, it created a sensation in the district, on account of the patient's reputation as a "holy man." 2. One eye counted fingers at six metres—a poor result, after a free escape of vitreous; the patient's vision before operation was confined to the perception of hand-movements before the eye. 3. One eye counted fingers at two metres—a poor result, due to an escape of vitreous resulting from too small a section. 4. One eye could detect hand-movements at a distance of three metres—a satisfactory if poor result when it is considered that there was a complete posterior synechia to be dealt with. The lens was wrenched out by means of a vectis, and the patient was more than satisfied, as before operation he could only with difficulty distinguish light from darkness. 5. One eye remained in *statu quo ante* after an apparently successful operation and an even recovery. Fundus changes were present.

The results therefore stand thus:—

—	Cases.	Percentages.	
Successful as proved by test dots...	61	79 22	94·80
Successful as shown by ability to count fingers easily with naked eye	10	12·98	
Successful (remarkably so, when the circumstances of the case are taken into account—*vide* 1 above)	2	2·59	
Very poor results...	3	3 89	5·19
Failure	1	1·29	
Totals	77	99·99	

PROPOSED SMALL-POX HOSPITALS FOR WORCESTERSHIRE.—Following on its report the committee appointed by the Worcester County Council to inquire into the necessity for establishing isolation small-pox hospitals has issued schemes for the various districts. For Evesham Borough District and the rural districts of Evesham, Pershore, and Tewkesbury it recommends the erection of a hospital for 12 beds at an estimated cost of £1100. Malvern Urban District, Wortley Rural District (south of Teme), and Upton-on-Severn Rural District will have a similar hospital provided. A hospital for 12 beds, costing £1100, will be erected for the rural districts of Wortley (north of Teme), Rock, and Tenbury. In connexion with the King's Norton and Northfield Urban Districts and Yardley Rural District it is recommended that a hospital with 20 beds should be built, and for the urban districts of Lye and Wollescote, Oldbury, and Stourbridge, and Halesowen Rural District a hospital for 16 beds, costing £1150. If the whole of the hospitals are provided out of one county fund a rate of 1$\frac{5}{16}$*d.* will be required. The question as to what shall be done is to come up for decision at the next meeting of the county council

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF ENTERECTOMY FOR STRANGULATED FEMORAL HERNIA.

BY J. R. RONALD MCCRINDLE, M.B., C.M. GLASG.

THE patient was a married woman, aged 41 years, and was admitted into the North Riding Infirmary, Middlesbrough, on Jan. 7th, 1902, at 3.30 P.M., suffering from a strangulated femoral hernia on the right side. She stated that the hernia had "been down" for seven years except for eight months during pregnancy three years ago. She was said to have vomited continuously since noon on the day previous to admission. After preparation of the patient I proceeded to operate about 5 P.M. with the assistance of Dr. J. Donaldson, the senior house surgeon. The swelling was of about the size of a cricket ball and was tense. On cutting down and opening the sac a quantity of dark-coloured fluid escaped and the bowel was seen to be gangrenous. The constriction was very tight, but after having nicked it I was enabled to pull down sufficient bowel to perform enterectomy which I decided to do, as there was practically no distension above the constricture and the patient was in fair condition. Five inches of bowel were excised. No omentum was present. I made the anastomosis by means of a Murphy's button ($\frac{11}{16}$ths of an inch). The cut edges of the mesentery were overstitched and the puckered portion buttressed on either side of the line of junction of the bowel in order to protect the weak portion at the reflection of the mesentery. The opening into the peritoneal cavity was enlarged sufficiently to permit the passage of the bowel containing the button. After separation and ligature of the sac the whole wound was closed by means of successive layers of buried catgut sutures and the edges of the skin were brought together with silkworm gut. The time from commencement of the anæsthesia to completion of the operation was 35 minutes.

The woman was somewhat collapsed on return to the ward, so 10 minims of liquor strychninæ were administered hypodermically and a stimulating enema was given. She had a fairly comfortable night and slept about five hours.

On the following day a simple enema was given with good result. Her temperature was 100° F. She was allowed small quantities of plasmon with a teaspoonful of meat juice by the mouth every two hours and a meat suppository every six hours. The wound was dressed and the stitches were removed on the eighth day. The button was passed on the sixteenth day, after which the patient's diet was made more liberal and was gradually increased to the ordinary amount. Her bowels acted daily. She was kept in bed for six weeks and was discharged on Feb. 28th cured.

Middlesbrough.

POST-VACCINAL LICHEN URTICATUS.

BY R. W. MARSDEN, M.D. VICT., M.R.C.P. LOND., &C.,
LATE MEDICAL SUPERINTENDENT, MONSALL FEVER HOSPITAL, &C.

THE following case is particularly interesting at the present time in view of the fact that the medical attendant could not free his mind from the suspicion of small-pox, and it is, I think, further worthy of note since I can find no recorded case agreeing in every particular.

The patient was an adult female who had been successfully vaccinated a month previously. At the time of my visit there were two dry and almost completely healed vaccinal ulcers on the right upper arm and the patient informed me that an inflammatory œdema had been present, extending beyond the middle of the forearm. Previously to the occurrence of the rash there had been no symptoms suggestive of the invasion of an acute disease nor had there been any glandular infiltration or septic absorption or administration of drugs likely to give rise to it. The first indication of change consisted of a feeling of irritation at the site of the recent vaccination. This persisted for a couple of days and then the appearance of the rash was noticed on the hands and arms. I saw the patient 24 hours after the rash made its appearance and found its distribution as follows: the hands and fingers, both palmar and dorsal surfaces, the front and back of the forearms, and to a much less extent the upper arms. On the lower limbs the plantar and dorsal surfaces of the feet were affected and the adjoining portions of the legs, whilst the rash was present, though less profuse, on the thighs. In addition there were an isolated collection of papules over the lower part of the sternum and a few papules along the border of each pinna. In general the rash may be described as of a papulo urticarial character, the papular appearance being most marked on the backs of the hands and fingers, a feature which had undoubtedly occasioned the suspicion of small-pox. An examination of these parts alone was, in fact, very suggestive of this disease. There were, however, no rash on the face, no accompanying pyrexia, and, as I have said, no history of recent acute illness. The papules, which were also present on the feet, were bright red in colour, about one or two lines in diameter, circular, and faded on pressure; they were softer than those met with in variola and exhibited a tendency to run together in patches. On the palms and palmar aspect of the fingers they formed bright red, discrete, tender macules, not raised but still round, and especially in the former situation were as much as from two to three lines in diameter On the arms and legs the spots were soft, flat-topped, in general rather of an urticarial character, varying in size from one to three lines and everywhere accompanied by itching. Many spots had a narrow inflammatory areola but the surrounding redness and œdema were best marked on the pinnæ. In the centre of a few there was a minute scab and on the surface of some others an appearance as though vesiculation was beginning, but both of these manifestations I attributed to the scratching, squeezing, or rubbing to which the patient resorted on account of the irritation. The further course of the eruption was absolutely unlike that of variola as there was no steady progress to vesiculation and pustulation—on the contrary, the spots tended to coalesce over considerable areas, forming a uniform erythema, and then faded.

The interest in the case lies not only in the fact that it was mistaken for small-pox but further in the late appearance of the eruption after vaccination. In this instance a full month elapsed, though, according to Dr. T. D. Acland in Clifford Allbutt's "System of Medicine," post-vaccinal eruptions make their "first appearance between the ninth and fifteenth days," being "always contemporaneous with vaccination."

Manchester.

A CASE OF NUTMEG POISONING.

By ROBERT A. PITTER, L.S.A.

QUITE recently I was called during the night to see a young woman who was stated to be "in a fit." I found her in a collapsed condition, muttering unintelligibly; her extremities were clammy, her pulse was hardly perceptible, and her pupils were somewhat dilated and reacted feebly to light. The symptoms were suggestive of alcoholic poisoning but her breath smelt unmistakeably of nutmeg and I then elicited that she had taken a whole nutmeg, grated, in a wineglassful of gin an hour or so previously. On asking her friends why she had done this I was told that "she was so afraid of having another child." It appeared that the catamenia had been delayed two weeks and, dreading pregnancy, she had taken the advice of some female friend with the result above mentioned. I afterwards made some inquiries and learned that there is a prevailing impression among the domestic servant class that nutmeg is an emmenagogue, although such a large dose is perhaps unusual. Her general condition improving I contrived to empty her stomach of its contents. She remained in muttering delirium throughout the night and slept heavily nearly all the next day, when she awoke apparently recovered. The catamenia followed, accompanied by much pain.

I should be grateful to any reader of THE LANCET for information as to other cases in which toxic effects have been produced by this spice.

ST. GEORGE'S HOSPITAL.

TWO CASES OF INTESTINAL OBSTRUCTION

(Under the care of Mr. G. R. TURNER.)

THE former of the following two cases is a very striking instance of the benefit resulting from laparotomy in tuberculous peritonitis and it is especially valuable as it demonstrates clearly the rapid removal of tubercles deposited in the peritoneum. It is very rarely, indeed, that an opportunity is afforded of seeing the peritoneum soon after a laparotomy for tuberculous peritonitis. Although no satisfactory explanation has been given of the way in which this treatment acts, yet there can be no doubt about the satisfactory character of the results. F. Treves estimated[1] the mortality directly due to the operation as only 2·5 per cent.; the percentage of permanent recoveries is difficult to state with any exactness but Hartmann and Aldibert[2] claimed that 46 cases recovered out of 48 Those cases are the most satisfactory in which no other organs are affected with tubercle. The incident in this case of the retention of a Murphy's button is one by no means rare; it is especially frequently met with when a portion of the bowel has been short-circuited. It is very rare for the button to do any harm when thus retained and in most cases it passes ultimately spontaneously The second case raises the question as to the desirability of colectomy in intestinal obstruction produced by a new growth. Each case must be decided on its merits. If the general condition of the patient will permit it a primary resection of the affected portion of bowel with anastomosis of the healthy intestine is certainly best, for the risk of a second operation is avoided; but if the patient is much collapsed it is better to do a colostomy and to postpone to a subsequent occasion the resection of the bowel.

CASE 1 *Intestinal obstruction due to tuberculous peritonitis, anastomosis of the ileum with the transverse colon; recovery, with disappearance of all tubercle within 45 days of operation.*—A girl, aged 11 years, was admitted into St. George's Hospital on May 14th, 1901, with the following history. Five days previously she had been attacked with sudden abdominal pain, frequent vomiting, and the passage of blood-stained motions. The child had been in bad health for several months She was a thin, dark little girl of the fine tuberculous type and was flushed and looked very ill Her tongue was covered with a brown fur; the pulse was 142 and weak and the temperature was 98° F The abdomen was moderately distended and moved well on respiration Nothing could be felt per rectum which contained some slimy mucus In the right iliac fossa a mass of about the size of an orange could be distinctly felt. It was dull on percussion and tender When she was placed under an anæsthetic some enlarged glands could be distinctly felt in this situation.

The abdomen was opened in the middle line. A quantity of enlarged tuberculous glands were found scattered throughout the mesentery and the peritoneum generally was studded with miliary tubercle. The lower ileum was enormously distended, injected, and vascular, whilst the ascending colon was collapsed and empty. In the right iliac fossa, in addition to some enlarged tuberculous glands, there was a large mass of matted intestine which included the cæcum and appendix, looking like a very firm intussusception with complete obstruction As it seemed impossible to reduce this and as in the child's precarious condition it was very inadvisable to attempt removal of this mass of matted intestine it was decided to anastomose the ileum some inches away from the obstruction with the transverse colon by means of a Murphy's button. This was accordingly done and the union of the two portions of bowel was strengthened by a few Lembert stitches. A Keith's drainage-tube was inserted at the lower end of the wound. The latter was kept in for four days after the operation and gave vent to some sanious discharge only. The child did well after the operation and on the 18th she passed flatus by the rectum. On the 20th a quantity of pus, the source of which was not apparent, passed from the lower end of the wound. *There was practically no rise* of temperature or fever. The bowels were opened after an enema on the 21st, a week after the operation. The stitches were removed on the 31st. The child by this time had a daily action of the bowels and appeared to be quite well. The Murphy's button, however, had not been passed. On June 25th examination by means of the x rays showed this to be in the right iliac fossa, as if it had fallen back into the ascending colon, and at a consultation on the 26th a second laparotomy was advised, the button to be dealt with according to circumstances. On the 28th (45 days after the first operation) the abdomen was opened in the right semilunar line. There was absolutely no trace of tubercle about the peritoneum; the miliary nodules and the enlarged mesenteric glands seen at the former operation had both absolutely disappeared. The intestines were perfectly healthy in every respect but were firmly adherent in the right iliac fossa. The Murphy's button could be felt deeply placed in this situation and surrounded by adherent intestines. It was therefore resolved to leave it.

---

[1] THE LANCET, Oct. 26th, 1895, p 1030

[2] Annales de Gynécologie et d'Obstétrique, June, 1892.

The child made an uninterrupted recovery from the operation and was sent in July to the convalescent hospital at Wimbledon. She was under observation there until September and has recently been seen. She seems perfectly well in every respect and suffers no inconvenience of any kind from the Murphy's button.

CASE 2 *Intestinal obstruction caused by malignant disease of the colon; colectomy; recovery.*—A woman, aged 59 years, was admitted into St. George's Hospital on May 13th, 1901. She had been losing flesh for the last four months and had had dyspepsia and constipation. On the 9th vomiting started and had continued until the morning of admission. There were much abdominal pain, referred chiefly to the umbilicus, and swelling. The last natural action of the bowels occurred on the 8th. An enema was administered on the 12th with small result and again on the 13th with no result. The patient's condition on admission was as follows. She was a grey-haired woman with sallow complexion and was obviously wasted; the skin was inelastic and wrinkled. The central part of the abdomen was distended and resonant and active peristalsis of the intestines was seen. There was no rigidity. No tumour could be felt. There was good abdominal movement on respiration. The rectum was capacious and empty; no tumour or stricture was to be felt. Her pulse was 120, the respirations were 28, and the temperature was 97·8° F. Dr. F. G. Penrose saw the case and agreed in advising operation.

Mr. Turner opened the abdomen below the umbilicus in the middle line. The cæcum was enormously distended, the appendix was normal, and the sigmoid flexure was collapsed but otherwise normal. The abdominal incision was now extended upwards to allow of examination of the parts above the umbilicus. The splenic flexure of the colon was then found to be the seat of a tight annular malignant stricture involving about one and a half inches of the bowel. No secondary growths were to be seen. The growth was resected with about one inch of healthy bowel on each side and the ends were sutured, Allingham's bone bobbin being used. A few Lembert stitches were also inserted. Some strips of gauze and a glass drainage-tube were passed down to the seat of resection and a tube was inserted to drain the pelvis. On the 14th the patient was much better. No pain or vomiting was present There was much serous discharge from the wound. On the 12th she was doing well; all plugging was removed. On the 20th the drainage-tube was removed. A good motion was passed by the bowel. On the 23rd there was some distinct fæcal discharge from the wound (? due to some slight sloughing at the seat of suture). On the 30th she was doing well. There was a slight discharge, no longer feculent, from the wound. The bowels were acting normally and good motions were passed. The patient was being fed on solid substantial food.

Remarks by Mr. TURNER.—The chief interest of Case 1 consists not so much in the intestinal obstruction with the concomitant pseudo-intussusception due to the tuberculous peritonitis as in the rapid disappearance of the tuberculous condition. Enlarged mesenteric glands numbering at least 20 or 30 and multitudes of miliary tubercles had entirely disappeared when the second laparotomy was performed 45 days after the first operation. That such disappearance follows operation is well known, but this case shows how quick that disappearance may be and how soon a diseased intestine and mesentery may recover from tuberculous invasion. Any attempt at dealing with the matted ileum and cæcum with a view to their disentanglement or resection in the child's very grave condition would most undoubtedly, in my opinion, have proved quickly fatal. To use Murphy's button seemed to be the quickest and the safest course to pursue, and although the button has not even yet come away its presence gives rise to absolutely no symptoms. It should have been mentioned that at the first operation a minute perforation was seen in the softened distended ileum which was closed by a Lembert's suture. It was not more than a pin-prick and seemed to follow the application of a Spencer-Wells clip to a bleeding vessel in the neighbourhood. All the lower part of the ileum was reddened, soft, and hooded, as it were, over the cæcum and appendix which were in consequence, except for the tip of the latter, obscured from view. There was little if any fluid in the peritoneal cavity.

In Case 2 colectomy was done during the actual bout of intestinal obstruction which rendered its performance more difficult and led me to use a drainage-tube and gauze packing, as I had not implicit confidence in the condition of the distended bowel which was sutured. I had seen, too, in another case where the bone bobbin was used for a colectomy some slight fæcal leakage afterwards. The depth of the parts operated on would have made direct suture very difficult and have dangerously prolonged the time of operation. The successful issue of the case was largely due to the gauze drainage employed, as there can be no doubt that there was some little leakage from the bowel 10 days after the operation.

For the notes of the cases I am indebted to Mr. T. C. English.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

The Relation of Malignant to Rheumatic Endocarditis.

A MEETING of this society was held on April 8th, Mr. W. J. WALSHAM, the President, being in the chair.

Dr. F. J. POYNTON and Dr. ALEXANDER PAINE communicated a paper entitled, "A Contribution to the Study of Malignant Endocarditis." They had been led to study malignant endocarditis in the course of an investigation upon the pathogenesis of rheumatic fever. The relationship between the two diseases was, they believed, a very close one and this was especially true of certain cases of malignant endocarditis which were associated with a previous history of rheumatic fever and during the course of which rheumatic manifestations were apt to occur. Now that rheumatic valvulitis was known to be infective "malignant endocarditis" was, they thought, a more accurate term than "infective endocarditis." The question arose whether some of these malignant cases were not really rheumatic. The idea was not an original one but the possibility of complete proof had been heretofore impossible since an exciting cause of rheumatic fever had been unknown. The evidence in favour of such a cause being a diplococcus was now extremely strong and this seemed a fit occasion to investigate once more the relationship of these two diseases. The result of the present research had led them to the conclusion *that there was a group of cases of malignant endocarditis rheumatic in origin.* The chief reasons for this conclusion and for which evidence was adduced in this contribution were: (1) that clinical experience favoured the assertion and clinical cases were narrated in support of this statement; (2) that the study of the morbid anatomy of the diseases was also in its favour; and (3) that bacteriological and experimental investigations were also in accord with the view, because a diplococcus could also be isolated from cases of malignant endocarditis which could be grown in pure culture, which would reproduce that disease in rabbits, and which resembled the diplococcus of rheumatic fever in its morphology and cultural characteristics. Moreover, *the diplococcus of rheumatic fever would produce* malignant endocarditis in rabbits on the one hand, and the diplococcus from certain cases of malignant endocarditis would produce rheumatic fever in rabbits on the other. Finally, every grade of valvulitis, from simple to malignant and *vice versâ*, could be produced by these two diplococci. A valuable series of macroscopical and microscopical specimens, lantern slides, and drawings were exhibited in support of these statements. The details of the investigations of Dr. Poynton and Dr. Paine were grouped under three headings: (1) clinical, experimental, and pathological observations; (2) histological details; and (3) bacteriological data. The clinical cases, seven in number, exemplified the type of endocarditis upon which they had been engaged and the gradations between it and rheumatic fever. The experimental investigations demonstrated the reproduction of malignant endocarditis; the transition of malignant endocarditis to rheumatic fever; the production of malignant endocarditis by the diplococcus of rheumatic fever; the production of rheumatic fever in a rabbit by inoculation with the diplococcus of rheumatic fever, and some months later malignant endocarditis by a second inoculation with the same organism; and lastly, some results of inoculation of rabbits with the "streptococcus pyogenes." Secondly, the histological details pointed to the wide distinction between the vegetations upon the cardiac valves in rheumatic valvulitis and those of malignant endocarditis. In the former no diplococci were present in the necrotic tissue; in the latter there were numerous diplococci in the necrotic tissue. Between these extremes there was every grade. The tendency of malignant endocarditis to occur in damaged valves was not, they thought, due to the affinity of the diplococci for such damaged tissues but to the lack of resistance of the damaged tissues. Thirdly, so far as they had ascertained, the two diplococci only differed bacteriologically in the smaller size and more rapid growth of the diplococcus in malignant endocarditis. These distinctions were not, in their opinion, sufficient to constitute diplococci as separate and distinct organisms. Allusion was made to the acid-producing properties of these organisms and the possibility that these properties played some part in the rheumatic processes. The concluding part of the paper dealt with observations upon *rheumatic*, *rheumatoid*, and septic processes. The difficulties of such an inquiry were very great, but the onus of proof that rheumatic fever might result from varied infections lay with those who upheld that view. Dr. Poynton and Dr. Paine did not think that rheumatic valvulitis was the only manifestation that might become malignant, but that both pericarditis and arthritis might also take this course. They desired to express their thanks to Dr. W. B. Cheadle and Dr. D. B. Lees for the clinical cases and to Mr. H. G. Plimmer for valuable advice and assistance.

The discussion of this communication was adjourned until the next meeting.

OBSTETRICAL SOCIETY OF LONDON.

Primary Tuberculosis of the Cervix simulating Cancer.—Exhibition of Specimens and Drawings.

A meeting of this society was held on April 2nd, Dr. Peter Horrocks, the President, being in the chair.

Dr. A. H. N. Lewers read a paper on a case of Primary Tuberculosis of the Cervix simulating Cancer which he had treated by vaginal hysterectomy. The patient was a married woman, 36 years of age, who had never been pregnant. For nine months before she came under observation there had been a vaginal discharge which was blood-stained and slightly offensive. Bleeding had been noticed after coitus and also after using a vaginal syringe. She had had slight pain in the left iliac region for about five months. This did not appear to have been at all severe. The catamenia had been regular, lasting three or four days only, and not attended by any special pain. The patient's general health had been good up to 12 months before she came under observation. Then she found herself beginning to get weak and disinclined for exertion and to suffer from the local symptoms above mentioned. She did not think that she had lost flesh. One of her aunts had died from consumption but otherwise the family history was unimportant. On vaginal examination the condition of the vaginal portion of the cervix *seemed to be identical with what was found in many cases* of cancer. The vaginal portion appeared to be the seat of "a growth" which was friable and bled readily on examination. The uterus was freely moveable. Believing that the case was one of cancer of the cervix suitable for radical operation Dr. Lewers performed vaginal hysterectomy on Jan. 30th, 1896. The patient made a good recovery. He had seen her several times since and received a letter from her on Nov. 20th, 1901, in which she said that she "enjoyed fairly good health and had had no return of the bleeding." While she was in the hospital there was no evidence of any disease in other organs. When portions of the supposed malignant growth were sent to the Clinical Research Association for examination the report came back that there was no evidence of cancer but that the structure was tuberculous. Brief reference was made to the writings of Pozzi, Cullen, and Whitridge Williams, from which it appeared that primary tuberculosis of the cervix was an exceedingly rare condition.—Specimens of tuberculous disease of the body of the uterus, the cervix, and the vagina were shown by Dr. H. Russell Andrews, Dr. Williamson, Mr. J. H. Targett, and Dr. E. C. Croft, and were discussed in connexion with Dr. Lewers's paper.—Dr. M. Handfield-Jones narrated a case which had come under his observation in which the patient, a multipara, aged 30 years, had suffered for several years with strumous disease of both hands. Several fingers and parts of the metacarpal bones had been removed at different times owing to the presence of tuberculous disease of the bones and joints. For months the patient had been suffering from excessive menstrual losses and in the intervals from a foul vaginal discharge. Examination showed that the cervix was deeply excavated by tuberculous ulceration and that the mischief had extended to the upper part of the vaginal wall on the left side. As the patient would not submit to any radical operation the ulcerated cervix was thoroughly scraped and then Paquelin's cautery was freely applied to the base of the ulcer. Cicatrisation followed and two years later the patient was found to be free from any further spread of tuberculous disease in the genital tract but she had commenced to develop tuberculous lesions in her lungs. The good effect of the curettage and the use of the actual cautery was very manifest and might certainly be used with advantage for cases in which extirpation of the uterus was deemed undesirable.—Dr. Croft remarked on the importance and difficulty of diagnosing cases of tuberculous cervicitis. There was a closer resemblance of the symptoms in Dr. Lewers's case to those of cancer than in the case described by himself. Dr. Lewers's patient had had bleeding, pain, and some offensive discharge. Dr. Croft's patient had absolute amenorrhœa for many months, bleeding only taking place when examined. The growth was softer than in cancer and did not break away in the same crumbling manner. The papillary masses were easily detached and were more of the consistence of mucous polypi than of the vegetations of cancer. Dr. Croft on his first examination of the case concluded that the growth was not of the nature of any of the ordinary forms of cancer of the cervix, but he kept in mind the possibility of an early condition of botyroidal sarcoma, or myxoma of the cervix. The tuberculous nature of the lesion was, however, established by microscopical examination before operation was decided on.—In reply to a remark of Dr. Lewers, Dr. Croft said that tubercle bacilli had not been definitely demonstrated.—The President said he was surprised to hear that tubercle in the uterus in the majority of cases was confined either to the cervix or to the body, for in the only two cases that had come under his observation the whole mucous membrane from the os externum to the top of the uterus was affected and he had thus been led to think that tubercle differed essentially in this respect from cancer. Also in his own case and in Dr. Lewers's case the patients had never been pregnant. He was surprised to hear Mr. Targett say that it was easy to diagnose tubercle. Certainly it might be in the lungs, either clinically or post mortem with the naked eye, but in the tubercle of the uterus he thought it was difficult, and even where a piece had been cut out and investigated microscopically it had been pronounced to be sarcoma. He was under the impression that the specimen shown by Mr. Targett from the Guy's Hospital Museum was the same one to which he had referred. The patient was in a medical ward and he (the President) had seen her and had diagnosed from the condition of the swollen cervix which seemed filled with ovula Nabothi a follicular inflammation of the cervix. She was transferred to the care of Dr. A. L. Galabin who cut a piece out and after careful microscopical investigation came to the conclusion that it was sarcoma and removed the uterus by vaginal hysterectomy. The whole of the uterine mucous membrane was greatly thickened and diseased throughout. It was examined at the Royal College of Surgeons of England by Dr. J. F. Goodhart and someone else and tubercle bacilli were found.—The paper was also discussed by Mr. TARGETT and Dr. J. M. MUNRO KERR, and Dr. LEWERS briefly replied.

Dr. J. S. FAIRBAIRN showed a Unilocular Ovarian Cyst containing in its wall large solid masses undergoing necrotic change. The cyst itself showed no evidence of any twisting of the pedicle and was, in fact, a sessile cyst enucleated from underneath the broad ligament. The solid masses were of a deep purple colour and thus projected into the interior as a number of rounded bosses; on section they were very firm and hard and cut more like a fibroma than the solid adenomatous structures of an ovarian cyst. When fresh they were full of blood and had an appearance very like that of liver. Microscopically they proved to be adenomatous with a papilliferous arrangement. There was a very extensive extravasation of blood with thrombosis of vessels into the necrosed parts. The partial necrosis affecting only the solid masses was somewhat difficult to explain. As there was some calcification at the base of the cyst this might have interfered with the blood-supply.

Dr. AMAND J. M. ROUTH showed a specimen of a Fallopian Tube ruptured towards its fimbriated end in two places. The patient was a multipara, aged 25 years, who when about six weeks pregnant was seized with collapse and all the signs of intra-abdominal hæmorrhage. When the abdomen was opened the peritoneal cavity was found to be full of blood and the ovum in its intact membranes was found to be adherent to the edge of a rupture on the posterior aspect of the right Fallopian tube near the fimbriated end. The tube was ligatured off and removed and was then found to be ruptured both anteriorly and posteriorly. The patient rallied well from the operation and made an easy convalescence. When examined the ruptured tube showed the following features. It measured seven centimetres in its long axis. At the cut uterine extremity it was normal in size for one centimetre of its length but its imen was impervious. One centimetre from the cut end e tube widened out into a thin-walled sac, the distension eaching as far as the fimbriæ which appeared as so any finger-like processes proceeding from the sac; the bdominal ostium having been closed it was no longer aceable. The tubal gestation sac measured six centietres in length by 2·5 centimetres in width through s greatest diameter. The sac tapered at either exemity, being more or less fusiform in shape. The walls f the sac had ruptured both anteriorly and posteriorly, the ne tear in the distended condition measuring one centimetre y two centimetres, the other being two centimetres by two entimetres in extent. Both tears proceeded to within two entimetres of the fimbriated extremity of the tube.

Dr. ANDREWS, having shown a Photograph, two Drawings, nd the Pelvic Organs from a case of Congenital, or rather Infantile Prolapse of the Uterus, associated with Spina Bifida, Dr. BLACKER commented upon the case.

Dr. WILLIAMSON showed a specimen of Umbilical Cord containing four umbilical arteries and only one umbilical vein.

Dr. F. J. MCCANN showed a specimen of a Tubal Mole.

MANCHESTER CLINICAL SOCIETY.—A meeting of this society was held on March 18th, Mr. Herbert Lund, the President, being in the chair.—Dr. R. W. Marsden exhibited the following cases: 1. A child with apparently pure Mitral Incompetence, compensation being perfect. The rapidity of the pulse was only slightly increased, its volume and tension being very good, and beyond a marked accentuation of the second sound in the pulmonary area there was no further evidence of change. 2. A girl with Mitral Obstruction and Incompetence, the former being the more marked lesion. The rapidity of the heart-beat and the signs of hypertrophy of the right ventricle showed the absence of any great amount of reserve power and was anticipatory of the occasional failure of compensation which occurred, though at the time it was perfect, as evidenced by the loud second sound in the pulmonary area and the absence of any signs of venous stasis. 3. A girl with Mitral Obstruction and Incompetence associated with adherent pericardium due to a previous attack of rheumatic pericarditis. 4. A boy with Mitral Incompetence and Adherent Pericardium. The previous pericarditis had apparently extended to the left innominate vein, producing partial obstruction, as there was dilatation of the veins on the left side of the neck, over the upper part of the chest on the left side, over the left shoulder, and the left upper arm.—Dr. W. K. Walls (for Mr. A. Wilson and himself) introduced a patient with Fibroma Uteri whose case presented several features of interest. Three months earlier the tumour caused much abdominal enlargement, there being multiple tumours, each of about the size of two fists, or of a fœtal head, and one such occupied almost the whole of the pelvic cavity and caused the perineum to bulge considerably. The cervix could just be reached high up above and behind the symphysis pubis. The patient was, too, according to history, some four months pregnant but the physical signs of this were not clear owing to the fibroid complication. Nothing operative was done because of a recent and active infection with syphilis, and treatment was directed to this. A month previously premature labour came on spontaneously and a putrid six months' fœtus was delivered by Dr. Walls with difficulty. In showing the convalescent patient to the society Dr. Walls drew special attention to the rapid involution of the tumours post partum. The retro-vaginal tumour was rather less than a Tangerine orange in size and the other masses were diminished in corresponding degree, the uterus and tumours together being now entirely pelvic.—Mr. Stanmore Bishop showed an unusual case of Multilocular Ovarian Cystoma. He remarked that ovarian cysts were usually easy to diagnose and to treat, since they most commonly developed upwards into the general abdominal cavity and therefore did not disturb the relations of the parietal peritoneum, but that occasionally, as in this case, they appeared to develop downwards, separating the broad ligament folds, and embedded in the connective tissue beneath raised in their growth the pelvic peritoneum and the organs with which it was in more intimate relation. The patient, aged 54 years, was seen with Mr. G. Knapton of Moss Side in October, 1901. The emaciation of her chest and limbs contrasted characteristically with the enormously distended abdomen on the upper half of which well-marked veins were to be seen. Dulness on percussion was found over the whole of the abdomen, extending to the renal dulness in the right flank and leaving only two points at which resonance could be obtained—viz., just below the xiphoid cartilage and very posteriorly in the left flank. A thrill could be obtained extending right across the abdomen. The possibility of an immense hydronephrosis was considered, but this view was rejected because there had never been any symptoms connected with urination and the urine itself was normal. The doubt, however, somewhat unpleasantly recurred during the operation, when it was found that the mass extended far upwards behind the ascending colon. On Nov. 20th abdominal section was performed and [the tumour, which was cystic and multilocular, was enucleated from behind the pelvic and abdominal peritoneum. The main cyst contained 27 quarts of fluid. Over it, the cæcum with an appendix six inches in length and hypertrophied to the size of the little finger was found. The appendix was amputated. The large cavity left was partially obliterated by the falling back of the internal organs, the remainder being drained by gauze which was removed gradually during the next six days. The patient made a good recovery, but on Dec. 16th paralysis of the left arm and leg supervened with a large and deep sacral bedsore. These however, gradually improved, and on Jan. 19th, 1902, the patient left the surgical home with the bedsore healed but with some paralysis still remaining.—Dr. T. Arthur Helme read a paper upon Abdominal Section with Primary Tuberculous Peritonitis and Ascites and made some remarks on the differential diagnosis in such cases.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—The sixth meeting of the forty-sixth session of this society was held on April 4th, Dr. T. C. Meggison, the President being in the chair.—Mr. Bellamy Gardner opened a discussion on Anæsthetics in the course of which he recommended the use of a mixture of chloroform one part with ether two parts, administered upon a Rendle's mask, as being the safest and most convenient and suitable anæsthetic for use in general practice He was under the impression that chloroform was more often used outside the hospitals than was supposed and that it would be of great advantage bearing in mind the difficulty of other administration to urge the use of the mixture referred to on account of the lesser danger of the second stage of narcosis Under the influence of chloroform alone so many fatalities had occurred after the struggling and it was to this factor that Mr Gardner wished particularly to direct attention. It was his very strong belief that if no asphyxial factor was ever allowed to arise during chloroform narcosis the mere accurate adjustment of the dose was a very simple matter, but that, on the other hand, chloroform being a cardiac paralysant and asphyxia acting also secondarily upon the heart a very moderate degree of the latter turned the scale and produced the depression so commonly spoken of as due to chloroform vapour Unrecognised obstruction to breathing was in his opinion the cause of most of the fatalities — The President referred to the danger of conversation being carried on in the hearing of the patient while being anæsthetised as it might cause struggling —Dr F S Toogood said that he had had about 6000 cases of anæsthesia during the last seven years with only one death He considered that more depended on the experience of the anæsthetist than on the method adopted. A patient's behaviour under ether often disclosed the fact if he were addicted to drink Ethyl chloride might be given with a mask and had a longer effect than nitrous oxide He had done colotomies with cocaine but lately he had found that injection of distilled water had as much effect — Mr W H. Payne considered that the eye reflex was not to be depended upon as a sign of general anæsthesia. The reflex of the inner side of the thigh was more reliable Patients should not be forcibly held down.—Dr F Taylor said that he generally used the A.C E. mixture with Rendle's mask, but he found that the ether disappeared very rapidly and left the chloroform behind —Dr J P Henry described some operations which he had seen performed at the Beaujon Hospital at Paris by Dr Tuffier while the patient was under the influence of cocaine injected into the arachnoid sheath of the spinal cord —Staff-Surgeon W W Pryn, R.N, described a case which he had had where death nearly resulted from chloroform having been put by mistake in the bottle containing the A.C E. mixture.— Dr J H. Keay said that it was very rare to have a death from anæsthesia during labour He considered that there was a great future for local anæsthesia. He remembered when there were eight deaths under chloroform in a short time in Manchester —Dr T E. White said there was no doubt that more accidents occurred with small operations than big ones but that was probably due to less care He nearly had a death from bichloride of methylene about 15 years ago —Dr W Pitt Payne described a case where a patient nearly died under gas and ether An effectual way of preventing laryngeal spasm was to draw forward the tongue with tongue forceps.—Mr Joscelyn inquired whether putting down the head was of any use in cases where the heart failed.—Mr Gardner said that he agreed that there should be no talking He did not think that the alcohol was much good in the A.C.E. mixture Pinching the thigh was an excellent test. Persistent vomiting occurred in cases subjected to Tuffier's method. This seemed to be due to increase of pressure in the spinal canal.

BRADFORD MEDICO-CHIRURGICAL SOCIETY —A meeting of this society was held on March 25th, Dr H J Campbell being in the chair —Dr F W Furich showed a series of sections illustrating Cirrhotic Changes in the Livers of Pigs.—Dr T Jason Wood showed the following specimens (1) Ova and Embryos of Bilharzia Hæmatobia from the Urine of a Patient, (2) the Urinary Organs from a case of Primary Cancer of the Male Urethra, (3) Double Pyosalpinx removed by operation, and (4) Uterus removed for Procidentia.—Dr Campbell showed a Liver the seat of numerous abscesses probably of amœbic origin —Dr R H Crowley showed the following specimens (1) Membranous Colitis, (2) Carcinoma of the Rectum with Secondary Deposit, (3) Perforation of a Typhoid Ulcer in a portion of the Ileum which had been constricted by a Meckel's Diverticulum, and (4) Gumma of the Brain.—Mr C F M Althorp showed a specimen of Hydatidiform Mole.—Dr Crowley read notes on a case of Cortical Gummatous Meningitis The patient was a woman, 50 years of age, who complained in October, 1899 of severe headache and vomiting In June, 1900, she had several fits with convulsions involving the left arm and face, but with no loss of consciousness Examination revealed tenderness to percussion in the right frontal and parietal regions with some muscular weakness of the left side of the face. There was commencing optic neuritis on the right side. Under iodide of potassium she improved sufficiently to go to a convalescent home in July On August 15th she was admitted to hospital again with headache and vomiting and twitching of the mouth on the left side. Iodide of potassium was again given together with mercury, and by Nov 1st she was well enough to go home. She relapsed again in about a month and again improved under treatment In May, 1901, the headache was still bad and there was some return of the twitching and of the vomiting, this time no improvement took place under treatment. In July, 1901, Mr J B Hall trephined, but no tumour susceptible of removal was found. The headache and vomiting were completely relieved by the operation, but three weeks afterwards there was almost complete paralysis of the left side of the body She died six months after the operation Post mortem examination revealed an extensive tumour occupying the surface of the brain and involving the frontal and parietal regions. It was quite adherent to the dura mater and had penetrated far into the brain substance. Apart from this the brain was normal and there was no meningitis Dr Crowley discussed the point as to whether an earlier operation should have been undertaken He considered that in such cases the symptoms were due not merely to a localised gumma but to syphilitic changes in the surrounding vessels, and consequently that a curative operation was not likely to be successful.—The case was discussed by Dr Campbell, Dr A. C F Rabagliati, Dr Wood, and Dr J Metcalfe, and Dr Crowley replied —Mr W H. Horrocks, jun., read notes on a case of Abdominal Pregnancy which had been successfully treated by laparotomy The fœtus and membranes were shown as was a cast of the uterine cavity which had been passed a few days after the operation —Mr Philip E Miall read a paper entitled 'Protagoras on Medicine'

GLASGOW SOUTHERN MEDICAL SOCIETY —A meeting of this society was held on April 3rd Dr John Stewart the President, being in the chair —The discussion on the Curability of Phthisis Pulmonalis which had been adjourned at the previous meeting of the society was resumed by Dr Ebenezer Duncan In an interesting manner Dr Duncan reviewed the treatment of pulmonary consumption in the earlier part of the nineteenth century and pointed out that the open air treatment — so much lauded to-day — was advocated in England by Dr George Bodington as early as the year 1840 Speaking particularly of the curability of phthisis Dr Duncan gave a detailed account of cases which he had seen in private practice and in hospital in which undoubted cures had taken place. He had known patients to be completely restored to health and strength in whom there had been found all the signs of consolidation and excavation of the lungs and in whom the tubercle bacilli had been found abundantly in the sputum. Particular examples were described in which even in a short space of time remarkable improvement had taken place With regard to treatment he believed that a persistent germicidal course was very efficacious indeed Carbonate of guaiacol in large doses was of great service and he often gave creasote and cod liver oil (five minims in one drachm of oil) He strongly recommended inhalations of pinol and eucalyptol, and in the absence of catarrh of the bronchi he used formalin in from 10 to 20 per cent. solutions As regarded diet he believed in high feeding In addition to the ordinary diet his patients received four pints of milk per day He believed in the advantages to be gained by the open air treatment and he carried it out systematically in his practice —Dr Thomas Forrest remarked that when hæmoptysis was present the effect of treatment seemed to be more beneficial and the same result was found in phthisical patients with the rheumatic diathesis. He was inclined to think that by over feeding there was some danger of nephritis.—Dr T Kirkpatrick Monro spoke of the different types of pulmonary phthisis in which experience had shown that a favourable prognosis might be given and cited the hæmorrhagic form as an example He gave the details of some cases that had come under his observation in which recovery had taken place in a remarkably short period of time.—Contributions to the debate were made by Dr. W. Watson, Dr. A. S. Tindal, Dr. J. Coulson Howie, and Dr. T. Russell.—The President in a short speech reviewed the discussion and remarked that from the evidence laid before them the conclusion seemed to be that only to a limited extent could phthisis pulmonalis be regarded as a curable disease.

ROCHDALE AND DISTRICT MEDICAL SOCIETY.—A meeting of this society was held on April 3rd.—Mr. Herbert Lund read a paper on Failures and Successes in Urinary Surgery. He described cases illustrating the difficulty caused by a large lacuna magna in catheterising and also in the treatment of gonorrhœa, the distensibility of the female urethra for the removal of calculus, the evils of white wax in urethral bougies, and the advisability of sounding the bladder when performing circumcision in children. The dangers attendant upon even such a simple operation as circumcision were emphasised by reference to the case of an elderly man who had cerebral hæmorrhage with hemiplegia the day after the circumcision was performed. As regarded enlarged prostate careful catheterism was usually sufficient to give relief. The advantage of operation was immediate and only transient. Freyer's operation probably really consisted in the removal of an adenomatous mass which compressed the prostate. The suprapubic operation was the best in all cases of vesical calculus. Syphilitic ulceration of the bladder might be difficult to diagnose but it yielded to grey powder and iodide of potassium. Varicocele was best treated by the open method with excision of a length of vein. The most certain cure for hydrocele was excision of the sac. All these points were illustrated by reference to actual cases, and Mr. Lund also mentioned cases of renal calculus, hydatids of the kidney, and a case of intermittent hydronephrosis treated by nephrorrhaphy in which a large granulating surface was left and the patient was kept at rest in the dorsal position for three weeks with a successful result.—The President (Mr. R. Burdett Sellers), Dr. J. Melvin, Mr. W. Stanwell, and Dr. W. J. Kerr, made remarks, and Mr. Lund was warmly thanked for his interesting paper.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on April 4th, Dr. Arthur T. Davies, the President, being in the chair.—The President showed a specimen of urine from a healthy man which gave in a marked degree the nitric acid reaction with potassio-indoxyl sulphate.—Dr. H. P. Miller showed a specimen of Thoracic Hernia removed from a child, aged two and a half years, who died 10 hours after the initial symptom, vomiting. The hernia consisted of eight feet of large and small intestine that occupied the left thorax, displacing the heart to the right side of the mesial line. It occurred through an oval, smooth-edged, elastic opening, about one and a half inches in its longer diameter and about three-quarters of an inch in its smaller diameter, in the left leaf of the diaphragm about the lateral centre and towards the spine. There was no known strain to account for this condition. The small bowel was deeply congested.—Dr. B. G. Morison opened a discussion on the Management of the Third Stage of Labour. He held that no time-limit could be fixed before the uterus should be pressed to extrude the placenta, supposing that hæmorrhage did not take place then. But, roughly, a wait of 20 minutes was advisable before an attempt should be made to express the placenta. He objected to traction on the cord as a means of removing the placenta. Douching, vaginal or uterine, after a simple confinement he held to be unnecessary, while if a lacerated perineum were present he believed that the procedure was positively harmful. If the latter state were present a suture should be put in deeply. The suture he used was one of strong carbolised catgut. He held it to be important that when sutures were used they should be left for a week.—A general discussion followed.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—The seventh meeting of this session was held on April 4th, Mr. Alfred Cooper, the President, being in the chair.—The President announced that Sir Frederick Treves would deliver the Cavendish Lecture on June 20th and that its title would be "Some Phases of Inflammation in the Vermiform Appendix."—Dr. J. Allan read a paper on the Treatment of Malignant Disease by Electrical Currents of High Potential and Frequency.—Dr. A. Whitfield read a paper on a case of Peculiar Intolerance of the External Application of Mercury.—Dr. A. Mortimer read a paper entitled "Remarks on 1000 Anæsthetisations," most of which had been given by him during the past two years.—A discussion followed the reading of each paper.

Reviews and Notices of Books.

A Manual of the Practice of Medicine. By GEORGE ROE LOCKWOOD, M.D., Attending Physician to Bellevue Hospital, New York. Second edition, revised. With 103 Illustrations. London and Philadelphia: W. B. Saunders and Co. 1901. Pp. 847. Price 17*s.* net.

THIS text-book is probably better known in America than in England. In his preface the author states that his aim has been to present the essential facts and principles of the practice of medicine in a concise and available form. Dr. Lockwood has succeeded fairly well in his endeavours and a readable and trustworthy manual is the result. We especially notice that the author has evaded the fault which we have noticed in so many of the American text-books—namely, the needless sub-division of the systemic diseases. To adopt the classification followed by some authors of dividing diseases of the stomach, for example, into a large number of sub-groups, the differences being based on small pathological distinctions, can only prove confusing to the student and is of no practical clinical value. Dr. Lockwood has been wise in arranging the subject matter according to the admirable classification of Dr. Osler.

The etiology, pathology, symptoms, physical signs, complications, prognosis, and treatment of the various diseases are well described but the remarks on diagnosis are decidedly weak and the reader will search in vain for paragraphs on differential diagnosis. The clinical points are, however, well brought out and the student by comparing the accounts of the various conditions which may simulate each other should, as a rule, have no difficulty in coming to a conclusion as to the disease with which he is dealing. We would suggest, nevertheless, to Dr. Lockwood that in future editions more attention should be given to the subject of diagnosis.

The author remarks that in preparing this edition the whole book has been subjected to a thorough revision. Many portions have been entirely rewritten and a number of new subjects have been introduced. Among the new sections may be mentioned those on Bubonic Plague, Gastroptosis, and Reichmann's Disease. An account of the analysis required for the clinical investigation of gastric affections has also been supplied. Dr. Lockwood retains lobar pneumonia amongst the diseases of the respiratory system, although he defines it as "an infectious disease due to the diplococcus pneumoniæ." We prefer the more modern plan of placing a description of the disease amongst the "infectious diseases." If Dr. Lockwood's classification were to be followed throughout typhoid fever would have to be placed amongst diseases of the intestine.

The section on Diseases of the Nervous System is well written and the clinical descriptions are easy to follow. The pathology of the various diseases is briefly given but the student is not perplexed by an elaborate discussion of theoretical or contested matters. The various illustrations are beautifully reproduced and aid considerably in explaining the letterpress.

Thomas Henry Huxley. By EDWARD CLODD. Edinburgh and London: William Blackwood and Sons. 1902. Pp. 226. Price 2*s.* 6*d.*

WE have read this volume, which is one of the "Modern English Writers" series, with great interest. It gives the reader a realistic and striking picture of a man of great intellectual force and character who played many parts and always with distinction, and who occupied a very prominent and deservedly high position in the scientific and literary world. It is not too much to say that in whatever relation he is regarded Huxley united in himself a singular combination of qualities. He was a bold and original thinker who always kept in mind that the end of philosophy is the detection of law and unity in seeming multiplicity and discord and who strove to penetrate to the core of things and to follow no arbitrarily devised system or authoritative teaching but to trace out for himself the natural meaning and significance of the facts and of all of them Huxley manifestly had great intellectual honesty and courage and a singularly clear and robust style of thinking and writing. Nor was this all, for he was in no wise lacking in imagination and humour and he was full of that sense of pitifulness which, like subsoil-water, underlies the surface of most strong and noble natures. He was essentially combative, it is true, but much of this may be accounted for by the force and sincerity of his convictions and the truthfulness of his character, his conflict with adverse circumstances in early life, and his chronic ill-health.

In this small volume we have presented to us a study of Huxley in his different aspects as regarded from various standpoints: the man, the discoverer, the interpreter, the controversialist, and the constructor. Taking it as a whole we think an admirable sketch has been given of him. There is no need to allude to Huxley's great services to science, or to his literary productions and style of writing, for these are already well known to our readers. As Mr. Clodd says in his brief preface, he has made large draughts from the materials supplied by Mr Leonard Huxley in his very admirable "Life and Letters" of his father and from Huxley's own writings. We notice that some exception has been taken to the nature and treatment of the section devoted to the description of Huxley as a controversialist, but to have omitted it altogether or to have toned it down and emasculated it would have been tantamount to giving a most imperfect sketch of him. The ways in which men like the late Mr. Huxley and Sir James Paget, for example, would view everything relating to the spiritual faculties of man are, and always must be, different, but as this section does not properly fall within the purview of the medical or scientific journalist we are not called upon to notice it further.

Manual of the Diseases of the Eye for Students and General Practitioners By CHARLES H. MAY, M.D., Chief of Clinic and Instructor in Ophthalmology, Eye Department, Columbia University, New York. Second edition, revised. With 275 Original Illustrations and 36 Coloured Figures. New York: William Wood & Co. 1901. Pp. xiii. and 408. Crown 8vo. London: Baillière, Tindall, and Cox. Price 8s. 6d net.

THIS is a compendious and well-written text-book that may be taken as a companion to any systematic course of lectures on the eye. The author has had large experience in teaching and judiciously directs the attention of the student to the more important features of each form of disease. In testing the vision of illiterate persons he uses the letter E placed in various positions. We doubt whether this is superior as a test to the letter C suggested by Landolt. In the present edition a useful plate has been added showing the different organisms which are found in the chief forms of conjunctival, corneal, and lacrymal affections. The opportunity is thus afforded of comparing the gonococcus micro-organism with the pneumococcus, Koch-Weeks bacillus, the Morax-Axenfeld diplobacillus, the streptococcus, and the diphtheria bacillus as they are respectively seen under a magnifying power of 950 linears. As in all recent ophthalmological works the subjects of errors of refraction and of disturbances of motility are remarkably well given. The illustrations, both coloured and uncoloured, are unworthy of the text and might with advantage be replaced by other and better ones.

A Handbook of Hygiene. By A. M. DAVIES, M.R.C.S Eng., L.S.A., D.P.H. Camb, Lieutenant-Colonel R.A.M.C., late Sanitary Officer and Bacteriologist Army Headquarters, India; late Assistant Professor of Hygiene, Army Medical School, Netley. Second edition London: Griffith and Co 1901. Pp. 624. Price 8s. 6d.

THE first thing which will strike the ordinary observer on seeing this volume is that it has an unusually attractive appearance—a red leather cover, rounded corners and gilt edges—evidently a book for the pocket. A study of the contents confirms this view. The information is given in condensed form. It is not a text-book for the student but it is essentially the book on hygiene for military or civil practitioners serving abroad. The first edition appeared in the year 1894 and the principal alterations which are to be found in the present edition are in the sections which treat of the sanitary aspects of air, water, and food, soil and sewage disposal, and the causation and prevention of disease. Speaking generally, it may be said that the book has been brought well up to date and it is quite exceptional to find a statement so erroneous as that on p. 123, where the Chadwell spring of the New River Company is credited with yielding 4,500,000 gallons of water daily. This great yield of water was before the time at which the "crack in the basin" unfortunately occurred Although the book is not designed as a text-book of hygiene an advanced student might very profitably read it through when he begins to study the subject in order to gain a general idea of the outline of the problems with which he has to deal. The book would also be a good one for some men to read rapidly through just before they go in for one of the higher examinations in hygiene. The work will, however, prove most useful to those actually and actively employed in appointments dealing with questions of public health, and for such we know of no better work; the subject matter is good and the advantages to which allusion has already been made—the portability and general get-up of the volume—are likely to be appreciated

---

LIBRARY TABLE.

Tables of Organic Materia Medica for Medical Students. By WILLIAM WOOD, M.B, C.M., M.R.C P. Edin., Lecturer on Materia Medica and Therapeutics, Edinburgh School of Medicine. 1902 Quarto, pp. 215. Edinburgh: The Medical Supply Association.—These tables have been arranged to help students who are revising their materia medica prior to examination and for such purpose they are in every way suitable They should not be allowed to take the place of a recognised text-book, however, during the period of the regular lectures and the author has therefore supplied his readers with a blank page opposite to each table so that supplementary notes from lecture or text-book may be made. There are four columns in every table—(1) Name of Plant, (2) Part Used, (3) Preparations, and (4) Actions and Uses. In the second column, where crude drugs are referred to, the dose for internal use is also stated, and in many cases these doses are unofficial but perhaps useful for examination purposes. In the column of Actions and Uses we find many useful summaries. In some cases these are excellent, concise, and carefully worded; in others they are not so good. There is no mention of the soporific effect of apomorphine, though only a short time ago a large number of correspondents of the medical journals recorded instances of the value of the drug in that connexion. Under the heading of the Uses of Coca the author says that the truth of the statement that the leaves of coca, when chewed, enable persons to undergo great muscular exertion with little fatigue is exaggerated, and that athletes and others have tried this drug with disappointing effects. The late Mr. William Martindale, who made a very special study of coca and cocaine, was of opinion that coca does enable a great amount of fatigue to be borne with but little nourishment and that it does lessen the breathlessness caused by severe exertion, especially during mountaineering. There have been numerous accounts of walking feats in which coca has been used for its sustaining qualities and in 1893 during the army manœuvres great benefit was reported from its use. For the exact references we may refer the reader to the Extra Pharmacopœia. The only serious fault which we find with the book is the lack of a good index. There are indexes of various kinds, but they are scarcely satisfactory. Otherwise the book seems to us to be eminently suitable for its purpose and we recommend it to students.

A Concise History of Small-pox and Vaccination in Europe. By EDWARD J. EDWARDES, M.D. Lond. London: H. K. Lewis. 1902. Pp. viii. and 142. Price 2*s.* 6*d.* net.—This is a most admirable little book and a mine of information. It is, with the exception of the preface and a few closing words, simply a record of facts. If anything could convince an anti-vaccinationist of the idiocy of his belief it would be a perusal of this book, but as it is perfectly hopeless to argue with such persons in any way but those occasionally reported from that home of liberty and democracy the United States—namely, vaccination at the revolver's mouth—we will pass on to recommend all the clergy, the squires, and others who have it in their power to influence their neighbours to get Dr. Edwardes's book and to study its facts and figures.

The Underground Watering of Plants and Gardens. By the Holder of the Silver Medal of the Royal Agricultural Society of Ireland, &c. London: Ward, Lock, and Co. Pp. 77. Price 1*s.*—The author of this curious little book teaches that the surface watering of gardens is a great mistake and that it leads to an enormous waste which tends to cause water-famine among the poorer population of towns and cities. He advocates the use of certain "bamboo water-spears" of his own invention and asserts that they tend to lessen the quantity of water necessary for the support of plant life. We have not seen the instruments recommended, which may possibly possess the virtues attributed to them. The chief interest in the book consists in the fact that its author expresses clearly the views generally maintained by the engineers of the metropolitan water companies in regard to the wicked waste of water given to trees and flowers. "How great," says our author, "is the contrast presented between the wasteful extravagance of men who raise fresh loans on the rates to bring more water from the Welsh and Cumberland lakes, instead of economising the water already at their disposal, and the thrift of the Almighty, by whose wise providence wasteful exhaustion of the underground stores of moisture is prevented! Should we not take a lesson from this wise thrift of the Almighty by putting a stop to the enormous waste of water which goes on in consequence of surface watering in hot, dry weather in the many gardens by which our towns and cities are surrounded?"

Hindustani Self-taught with English Phonetic Pronunciation, containing Vocabularies, Idiomatic Phrases and Dialogues, Travel Talk, Military, Legal, Religious, Commercial, Shooting, Fishing Terms, Money, Weights, Measures, Indian Titles, Castes, Festivals. By C. A. THIMM, F.R.G.S. London: G. Marlborough and Co. 1902. Pp. 100. Price 2*s.*; bound in cloth, 2*s.* 6*d.*—We have turned over the pages of this little book from cover to cover, have lingered over some of them in doing so, and have arrived at the conclusion that it is what it pretends to be and that it fulfils what its title sets forth. It is surprising what a number of words, brief sentences, and information the author has contrived to bring together, to compress, and to arrange within a small compass in order to make easy the way o those desirous of acquiring some useful and available knowledge of Hindustani. We can recommend the book to thos for whom it is intended. Officers and others proceeding t India will find it a very useful companion on the voyage out. Much successful ingenuity is shown in the English phoneti pronunciation of Hindustani but, speaking from our own experience, we have found it very difficult to acquire th pronunciation of any foreign tongue in this way; in the cas of Hindustani a comparatively short residence in the country however, will do all that is needful in this respect. Th thing is to try to get a general idea of the language, a goo vocabulary, and to let no shyness stand in the way o attempting to use it; listening to the talk of natives an others conversant with Hindustani will soon do the rest

The Annual Charities Register and Digest for 1902, with a Introduction by C. S. LOCH. London: Longmans, Green and Co. 1902. Pp. cxcvi.–746. Price 4*s.*—Aristides, it wil be remembered, was ostracised and one Athenian gentlema voted against him because he was tired of hearing him calle the Just. We feel much the same sensations that mu have actuated Aristides's fellow-citizen when "The Annu Charities Register" makes its appearance. It is so goo that we have an almost irresistible idea to say somethin unkind about it. Mr. Loch's introduction is an admirabl piece of work; in the body of the book the seeker aft knowledge will find an account of every charity which worthy of support and the index to the work is a model what an index should be. In no object is zeal according knowledge more necessary than in alms-giving, and th Register and Digest will tell any person who wishes to b charitable where he may expend his alms to the be advantage. We must mention the one blemish that w have found and that is that in the list of "spiritu institutions" there are some which have no earthly right the name of charity.

The Medical Annual and Practitioner's Index, 190 Bristol: John Wright and Co. Pp. 774. Price 7*s.* 6*d.*– The twentieth issue of this most useful year-book is in n way behind its predecessors. A glance at the list of contributors will show that the editor of the work has selecte those well qualified to help him. Few, indeed, are th subjects upon which the busy practitioner will not find som information in this book. One of the articles which will b found most interesting is that by Dr. T. N. Kelynack on th outbreak of arsenical poisoning in the north of England i 1900. The article is well illustrated by coloured and othe pictures. Another very good and simply written article i that by Mr. A. St. Clair Buxton on Errors of Refraction an Accommodation. Part II. of the book is a *précis* of lega decisions on matter interesting to the medical professio given during 1901, and there are also accounts of new inventions, together with lists of inebriate homes and othe institutions and of books published during the year 1901.

John Bull: His Origin and Character and the Pres Condition of His Big Property, and Two Other Papers o Education. By CECIL REDDIE. London: George Allen 1901. Pp. 76. Price 6*d.*—"Pages of ephemeral verbiage" is good. For the expression we are indebted to Mr. Cecil Reddie. It fittingly describes the essays contained in thi little volume.

Profitable Fruit-growing for Cottagers and Small Holder of Land. (Gold Medal Essay.) By JOHN WRIGHT, V.M.H F.R.H.S., late Editor of the *Journal of Horticultur* London: W. H. and L. Collingridge. 1901. Pp. 127 Price 1*s.*—This is an enlarged and revised edition of a essay on profitable fruit-growing which obtained the gol medal and prize offered by the Fruiterers' Company in th year 1889. The present is the sixth edition which has bee published—a fact which clearly shows that the work as bee appreciated. The little book contains much useful information, is well illustrated, is clearly printed, and has a good index. The author holds the cheerful views in regard to profits which are usually entertained by successful writers on gardening but which are unfortunately less frequently held by the owners of orchards.

JOURNALS AND MAGAZINES.

Journal of Experimental Medicine Edited by WILLIAM H WELCH, M.D. Baltimore. Vol. VI., No. 2. Issued Feb. 5th, 1902.—Dr. S. J. Meltzer and Dr. W. Salant contribute a paper on the Effects of Subminimum Doses of Strychnine in Nephrectomised Rabbits, which is commented on in another column Dr. James Ewing writes an important communication entitled "A Contribution to the Pathological Anatomy of Malarial Fever." Amongst other conclusions at which he arrives is the one that it is frequently impossible to distinguish between the pigment deposits of malaria and those resulting from increased globulicidal activity of the serum in other diseases. The plates attached to Dr. Ewing's contribution are excellently reproduced. Mr E. B. Vedder and Mr. C. W. Duval (research students in the Rockefeller Institute of Medical Research) report the results of an investigation into the Etiology of Acute Dysentery in the United States. The main conclusion at which they arrive is that the cause of acute dysentery, whether sporadic, institutional, or epidemic, is the bacillus dysenteriæ of Shiga.

Middlesex Hospital Journal.—The issue of this journal for February contains the conclusion of an interesting article by Mr. C. Roberts on Surgery in the Boer War. The account given of wounds of the spinal cord is particularly noteworthy. The symptoms derived from such injuries were naturally most distressing and little could be done in the way of operations to relieve the condition. Mr. Roberts also describes lesions of the peripheral nerves due to bullet wounds. Extraordinary instances were met with in which a nerve as small as the median was pierced longitudinally by a Mauser bullet without being completely divided transversely. Dr C Price-Jones contributes an article on Methods of Hæmoglobin Estimation and details Haldane's modification of Gowers's hæmoglobinometer which obviates the defects connected with the use of artificial coloured solutions and tinted glass. "Some Definitions" by H. G. K. Y. are amusing "Examination Hall" is defined as "an unattractive riverside resort where examiners take in paying guests" A "lecture" is stated to be "a learned soliloquy frequently productive of deep sleep."

Journal of Anatomy and Physiology Conducted by Sir WILLIAM TURNER, K.C.B., F.R.S., D. J. CUNNINGHAM, F.R.S., G. S HUNTINGTON, F.R.S., A. MACALISTER, F.R.S., and J. G. M'KENDRICK, F.R.S. Vol. XXXVI. New series, Vol. XVI., Part III. April, 1902. Pp. 110. Price 6*s* London: Charles Griffin and Co.—The articles contained in his part are: 1. On the Development of the Head Muscles in the Newt, by F H. Edgeworth, M.B.Cantab, B.Sc.Lond., assistant physician to the Bristol Royal Infirmary. This article is illustrated by many drawings in the text. It is too intricate to abstract, but one of the incidental results of Dr. Edgeworth's observations is to show that he segmental value of the cranial nerves is to be determined rather by the morphological position of the muscles that they innervate or "represent" than by their arrangement in the mid and hind brain. 2. The Separate Functions of Different Parts of the Rima Glottidis, by W. A. Aikin, M.D Brux. The account here given contains some novel points due to Dr. Aikin having had exceptional opportunities of examining the movements of the larynx and his views are illustrated by two plates. 3. On an Unusual Form of Nasal Bone in a Human Skull, by W. L. H. Duckworth, M.A. The subject of the article was an ancient Egyptian. Mr. Duckworth also gives (4) a Note on the Irregularities in the Conformation of the Post-orbital Wall in Skulls of Hylobates Mülleri and of an Aboriginal Native of Australia. 5 An Ischiopagus Tripus (human), with special reference to the Anatomy of the Composite Limb, by James F. Gemmill, M.A., with two plates. 6. A Rare Anomaly of the Aortic Arch, by R. Stanley Taylor of Downing College and J. M. P. Groll of Selwyn College, Cambridge. 7. Anomalies in the Cervical and Upper Thoracic Region, involving the Cervical Vertebræ, First Rib, and Brachial Plexus, by Lawrence Dukes, B.A., and S. A. Owen, B A., of Trinity College, Cambridge. 8. A Contribution to our Knowledge of the Chemistry of Red Bone Marrow, by Robert Hutchison, M.D Edin, and J. J. R. Macleod, M.B Aberd. 9. Twelfth Report on Recent Teratological Literature, by Bertram C A. Windle, M.D. Dub. 10. On the Homologies of the Cerebral Sulci, by G. Elliott Smith, M.D. Sydney. 11. The Proceedings of the Anatomical Society of Great Britain and Ireland.

Journal of Physiology. Edited by Sir MICHAEL FOSTER, K.C.B., F.R.S., and J. N LANGLEY, F.R S. Vol. XXVIII., Nos 1 and 2. March 27th, 1902. London: C. J. Clay and Sons. Price 11*s*.—This part of the *Journal of Physiology* contains the following communications: 1. A Further Research into Fatigue of the Central Nervous System when caused by Electrical Stimulation, by A. G. Levy, M D. Lond., with eight figures in the text. 2 Path of Impulses for Inhibition under Decerebrate Rigidity, by A. Fröhlich, M.D, and C. S. Sherrington, M.D. Cantab, F.R.S. The path occupies a small, fairly limited area of the cross section of the cord. 3. Some Effects of the Ligature of the Renal Arteries in the Frog, by A. P. Beddard, M D Cantab. 4 The Effect of Local Injury upon the Excitatory Electrical Response of Nerve, by Francis Gotch, D Sc. 5. The Innervation of the Frog's Stomach, by Walter E Dixon, M.D. Lond., with 13 figures in the text. 6. Some Experiments on the Functions of the Medulla of the Kidney, by Francis D Boyd, M.D Edin. 7. The Relationship of the Spleen to the formation of the Blood Corpuscles, by D Noel Paton, M D, F.R.C.P. Edin., G Lovell Gulland, M.D, F.R.C P. Edin., and J. S. Fowler, M.D Edin., with 10 figures in the text. The conclusion at which these observers arrive is that in the animals which they examined—dogs, cats, and rabbits—there is no evidence that the spleen has any important action as a blood-forming organ. 8. The Influence of Subcutaneous Injections of Large Quantities of Dextrose on the Metabolism in the Dog, by James Scott, M.D. Edin. It increases it. 9. Note on the Absorption of the Nitrogen of Oatmeal by the Dog, by D. Noel Paton. 10. On the Residual Pressures in the Vascular System when the Circulation is Arrested, by Leonard E. Hill, M.B. Lond., F.R.S 11. Pancreatic Diastase and its Zymogen, by H M. Vernon, M.D. Oxon. 12. The Differences of Action of Various Diastases, by the same author. Dr. Vernon is led to conclude that malt diastase is an essentially different body from animal diastase; that salivary diastase is different from pancreatic; and that probably the pancreatic diastases of various animals are different bodies. 13. On the Digestion of Cane Sugar, by J H. Widdicombe, M.A. 14. The Proceedings of the Physiological Society, which include an article by E. H. Embley on the Causation of Sudden Death during the Administration of Chloroform; another by E. I. Spriggs, M.D., M.R.C.P. Lond., on a New Method of Observing Peptic Activity; and a third by Thomas Lewis on the Structure and Functions of the Hæmolymph Organs.

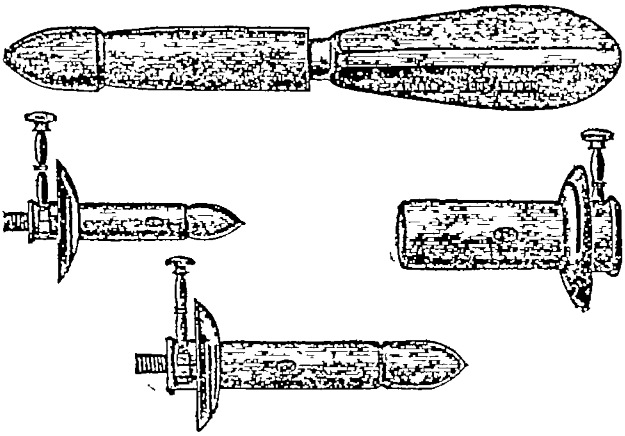
The *Veterinary Journal* for March commences with an editorial criticism upon that much-talked-of section of the War Office, the Remount Department. Although letting the authorities down lightly and recognising the difficulties which had to be faced, the article seems to infer that there has been a lack of business capacity shown throughout the whole affair and mentions certain salient points which must always be taken into account when estimating the actual cost of a troop-horse—such a point, for example, as transport and its necessary accompaniments in regard to forage, and the like. There is also a complaint regarding the cost of working the Indian Remount Department, as, upon the authority of the *Times*, each troop-horse passed into the ranks costs on an average £200. An inspection of the remount farms has been recently made by a distinguished body of army officers and as a result there is a suggestion that an Imperial Stud Department shall be formed to absorb the Remount and Civil Veterinary Departments and thus to bring them under one head. Clinical articles are given on Sarcoptic Mange of the Ox and Demodactic Mange of the Dog and there is an interesting illustrated case of an Actinomycotic Tumour removed from a Cow's Mouth. The remainder of the pages are devoted to extracts from foreign journals, reviews of books, and papers read before various veterinary medical societies during the previous month.

The *Veterinarian* for March has a dearth of clinical articles which seems to show either a very great apathy amongst the members of the veterinary profession or else that the usual recrudescence of disease which comes in the spring has made practitioners so busy that they cannot find time to put their pens to paper. The journal commences with a lengthy extract from a recently published work on Surgery, and is followed by others on Liver Fluke, the Development of Knowledge Concerning Animal Diseases, and Live Stock in Russia. These are followed in turn by a few extracts from foreign journals, some remarks on Current Topics, and Science Notes. The dearth of original matter is a subject for regret.

New Inventions.

SET OF TROCARS AND CANNULÆ FOR EMPYEMA.

MESSRS. ARNOLD AND SONS, London, have made for me a set of special trocars and cannulæ for use in certain cases of empyema. They are flattened from side to side and not circular as usual in other trocars, to enable them to pass through an intercostal space with greater ease. The cannulæ are made of silver and they can be left *in situ* for 10 days if necessary. The trocars are of very hard steel and in consequence of their shape the end and the cutting edge project further than in the ordinary form. To minimise the danger to deep parts when the instrument is used each cannula is fitted with a moveable shield, being fixed at any depth by a screw as in Durham's tracheotomy tube. The shape of the shield is similar to that of a bivalve tracheotomy tube, but it is perforated by two long slots placed in such a manner that whatever be the inclination of the ribs the tube can be kept in position by tapes threaded through these slots and passed straight round the chest. The set consists of three, with one handle which screws into all the trocars. The sizes are as follows: 1. Small, $\frac{5}{16}$ inch × $\frac{1}{8}$ inch and $1\frac{9}{16}$ inches long. 2. Medium, $\frac{7}{16}$ inch × $\frac{3}{16}$ inch and $1\frac{9}{16}$ inches long. 3. Large, $\frac{5}{8}$ inch × $\frac{1}{4}$ inch and $1\frac{9}{16}$ inches long. The above a inside measurements; the length is the effective length viz., from the shield to the end of the cannula. The chi use which I have put this instrument to, and in which I ha found it to act extremely well, is to drain an empyema aft incision of the skin under eucaine administered hyp dermically in those cases where the administration of general anæsthetic is especially dangerous on account of t condition of the patient.



WILLIAM TURNER, M.S. Lond., F.R.C.S. Eng.,
Senior Assistant Surgeon, Westminster Hospital; Surgeon,
Royal Hospital for Diseases of the Chest, City-road, E.C.

LECTURE 49.[1]

Thursday Evening, April 1.

On the Different Amputations.

Operations are now much less frequently performed tha they were in the days of our ancestors, owing to the grea improvements which have taken place in surgical scienc Many of the diseases which were formerly considere incurable can now be easily cured by modes of treatmen corresponding with our increased pathological knowledg Many accidents, for example, where the parts are muc lacerated, and for which the ancients would have operated we leave to nature, by whose influence the different repara tive processes will be set in action and the injured lim restored to health and utility. When amputation is nece sary, nature will occasionally even perform this operatio unassisted by art; in mortification of the feet it ofte happens that the leg will be amputated by nature a effectually as though it had been accomplished by th amputating knife. At Guy's Hospital there is at the presen moment a case of this description. You have seen, in th case which I allude to, first, a division of the skin, then th division of the muscles shorter than the skin, and lastly, th division of the bones; the fibula has already separated, an the exfoliation of the tibia is rapidly going on. Nature i this case if left to herself, would, without doubt, accompli the amputation of the leg, but the safety of the man requires I think, that the remainder of the bone should be divided b the saw, for if this be not done, the long continued excitement may wear out the powers of the constitution.

Diseased joints used very frequently to lead to the per formance of amputation, in the young as well as in old age but amputation is much less frequently performed at th present day, in consequence of such disease, than some year back; even diseases of the joints of the upper extremities o children give rise to amputation much less frequently tha in the days of our forefathers, but in chronic diseases o the ankle and knee, amputation is still very commonly per formed; there is, however, a marked distinction in thes chronic enlargements; one variety may be called congenital which exists from the birth of the child, and the other i from some debilitating cause which produces the complain after birth; as the constitution therefore was radically wea or vitiated in the former of these affections, you canno expect that such permanent benefit will result in that case as in the latter, where the constitution became affected from some accidental circumstance.

With respect to diseases of the ankle and knee joints amputation for such complaints will occasionally be nece sary both of the leg and thigh; indeed chronic affections o the ankle and knee give rise to amputation as frequently a diseases in any parts of the body. For compound fracture we seldom amputate directly: they are seldom so severe a to require immediate amputation, and it is not until gangren or disease of the bone has taken place, that it is deeme necessary to amputate; compound fractures, however, from the superior manner in which they are now treated, do much better than formerly, and very severe injuries of this descrip tion will often terminate most favourably, therefore upon th whole, amputations are much less frequently performed a the present epoch than in the days of our ancestors.

---

[1] Excerpt from report of lecture delivered by Sir Astley Cooper in th theatre of St. Thomas's Hospital.

THE LANCET.

LONDON SATURDAY, APRIL 12, 1902

The Will of Mr. Rhodes.

THE will of CECIL RHODES is a monument of the man, exemplifying in itself the vastness of his ideas, the loftiness of his ambitions, and the minute attention to detail with which he was accustomed to organise his designs. His intention to assist the welding of the British Empire into a more powerful and harmonious whole by promoting educational inter communication between the mother country and the colonies is assured of success, while the recognition of the many aims and interests that Great Britain and Germany have in common is to our thinking as shrewd as it is generous. The medical profession will have learned with gratification that this prescient man saw the influence that is played in the development of peoples by medical science His recognition of the claims of medical science upon his magnificently-planned munificence shows a sense of the part played by medicine in the civilising of the world, it proves also an appreciation of the fact that in spite of all recent progress and discovery science has still wide realms to explore, in the investigation of which money is necessary to equip the explorer Mr RHODES's reference to the features of medical education at Edinburgh and Oxford is peculiarly interesting Throughout the portion of his will which deals with university education he never loses sight of the social aspects of Oxford life as he knew it. He is aware of the high reputation of the University of Edinburgh which, he estimates, has at least 50 young men from Africa among its students, many of them attracted by its medical school. He is aware of the excellence of that medical school, but at the same time he sets high value on the residential system of which he himself has had personal experience at Oxford. For this reason he establishes the scholarships which he desires to found with a view to their recipients being educated at the University of Oxford. The terms and conditions of these scholarships are now known to everyone and we need not describe them. It has been suggested that in certain matters of detail they do not comply with what is required in the case of scholarships at Oxford. Presumably, if any difficulties in these respects arise with regard to the appointment of students such difficulties in the case of gifts of so great importance will easily be got over It also may be held that the scholarships designed by Mr RHODES are not, strictly speaking, university scholarships at all, but, rather, scholarships to be awarded by the trustees of Mr RHODES's will, without any intervention or control by the university authorities, to members of particular colonies and States

With regard, however, to the relative educational facilities for medical students at Oxford and at Edinburgh Mr RHODES makes a suggestion the meaning of which is obvious though the testator had not the facts of medical education very clearly before him. He suggests that Oxford should "try and extend its scope so as if possible to make its medical school at least as good as that at the University of Edinburgh" Mr RHODES in his will shows intimate and modern knowledge of the conditions existing at his college and his university When the will was made he no doubt knew that there had been progress and improvement initiated in the matter of medical education at Oxford, so that the early training of the Oxford medical student in the purely scientific, or auxiliary, branches of his profession is thoroughly first class He also knew that as a centre of medical education Edinburgh deservedly enjoys a long-established and world-wide fame. When, however, he recommends the University of Oxford to extend its scope, and implies that it has, or could obtain, the power to make its medical school "at least as good" as that of Edinburgh, he would appear to have overlooked the circumstances which contribute to make medical education at Edinburgh University what it is, circumstances which are quite unattainable at Oxford whatever efforts the University of Oxford may be stimulated to make. Edinburgh as the capital city of Scotland, and one of its largest centres of population, is a medical centre, in the natural course of affairs, such as Oxford can never become Edinburgh in its world famous Royal Infirmary combines in one institution to a singular degree all that is necessary for the most complete course of clinical study The University of Oxford can do what lies in its power as a university for the education of its medical students, but it cannot possibly increase the Radcliffe Infirmary so as to make it a hospital comparable with the Royal Infirmary of Edinburgh Nor can the reputation for scientific teaching which is necessary to attract students of science from all parts of the world be built up in a day Edinburgh was a centre of scientific inquiry and teaching when Oxford and Cambridge were schools of academic learning that practically confined their attention to Latin, Greek, mathematics, theology, and to questions arising out of these studies. Cambridge has made a name for itself during the past 20 years as the school *par excellence* for the student of natural philosophy, and there is no reason why the University of Oxford should not expand in a similar direction and with similar success. But neither of the old universities can become a centre of medical knowledge; both, in the absence of large and varied clinical material, must be content with supplying exceptionally well grounded students to other medical schools and with rigorously examining these same students in the later stages of their careers. That this point was hardly clear to Mr RHODES we think must be allowed

We warmly congratulate the University of Oxford on all the benefits which it will receive from the enthusiasm and far-sightedness of its great *alumnus*.

◆

Mosquitoes and Yellow Fever in Havana.

GRADUALLY but, it would seem, surely our knowledge as to the zoological distribution of infectious disease is extending and with its extension the field whereon is fought the battle against diseases affecting the human species is shifted from man himself to what is called the intermediary host. It has been so with malaria, it has been so in a measure with plague, and it is so with the several parasitic diseases which will at once suggest themselves. Of diseases such as these man has no longer the sole prerogative, they can no longer be known exclusively as "human diseases." Scientific research has now, in a sense, transferred from man to the mosquito that veritable scourge of certain tropical areas, yellow fever. The brilliant and withal somewhat heroic experimental investigations of our American *confrères* have served to show almost conclusively that personal infection plays an altogether insignificant, if any, rôle in the spread of the disease—that, as with malaria so with yellow fever, it may be a case of "no infected mosquitoes no disease." Many of the researches as to the part played by mosquitoes in diseases common to man have been worked out in one or another portion of the British Empire which has, epidemiologically speaking, the fortune to possess within its limits all the diseases which mankind is liable to inherit or to acquire; but unfortunately for scientific patriotism the workers in the field have often owed allegiance to other sovereigns than our own. In the matter of yellow fever the workers have been American, as also has been the soil upon which the researches have been carried out and the conclusions applied.

As we pointed out in a leading article on June 15th, 1901, the investigations of Major Walter Reed and his colleagues have seemed to show that the prevention of yellow fever is largely bound up with the destruction of the *Culex fasciatus* or the prevention of its bites, and the military administration of Havana has lost no time in putting this theory to a practical trial. The result of the destruction of this mosquito and its potential progeny has been almost dramatic in its thoroughness, and the city of Havana is now pronounced to be practically free from yellow fever. Thus it comes about that the advent of the American administration at the close of the Cuban war has, according to the last annual report of Major W. C. Gorgas, surgeon, United States Army, and chief sanitary officer of the city, been speedily followed by the extirpation of a disease which has been endemic therein for the last 200 years. We are in entire accord with Major Gorgas that this is a matter of vast importance and that "this fact should be made known to the world as rapidly as possible." If the passage of time sets its seal upon the promise of 1901–1902 we are, as Major Gorgas observes, face to face with a prophylactic measure which is worthy to rank, at least in so far as the yellow fever areas are concerned, with the discovery of Jenner. We cordially trust that time may justify the prophecy which has been made in all good faith and upon apparently trustworthy grounds. But while provisionally accepting the remarkable figures placed before us we must be forgiven if we plead for time before finally acquiescing in the inferences which have been drawn from them. On looking at the table relating to the annual deaths from yellow fever in Havana for the last 45 years we note that the yearly toll ranged from 2058 to 51, this latter figure being exceptional in that there has been nothing within recent years under 103, the figure for 1899. Under the anti-mosquito *régime* for the first 10 months of the yellow fever year 1901–1902 there have been but *five* deaths and this unprecedented drop is certainly such as to suggest the operation of some quite new factor. Unfortunately Major Gorgas does not give us in the text of his reports many details as regards the method of attack adopted, but we gather that during the period under discussion Havana was a city full of "non-immunes" and that it was in unrestricted communication by rail with half a dozen infected towns. Commerce was not interfered with and no restraints were placed upon the admission into Havana of clothing and bedding from infected localities. As Major Gorgas tersely expresses it: "The only infected material from the towns looked after was the sick man, who was carefully sought out and screened from mosquitoes." This story is full of interest both for the epidemiologist and the administrator, and the English Government will be lacking in initiative if it fails to make detailed inquiries at once into all the circumstances so that, if the facts justify the imitation, the method adopted in Havana may be applied to the yellow fever areas of our Empire. From the tables in the report before us it appears that there have been very extensive operations in the direction of the application of petroleum, in intimating to householders the existence of larvæ on their premises, and in making cisterns mosquito-proof, but precise details are lacking.

As a matter of curiosity we have been led to examine the figures as to the prevalence of yellow fever in Vera Cruz from 1866 to 1900, and from these we find that the annual figures have ranged from 747 to *nil*, the totals on several occasions having been below 10. We quite accept the obvious criticism that the returns for Vera Cruz and Havana are not strictly comparable, but nevertheless the figures show that in large populations where yellow fever is endemic it is not unusual for the returns for any one year to present an absence of the disease in question. In thus enjoining caution we are anxious to accord all honour to the American military administration in Havana the results of which are so graphically portrayed by Major Gorgas himself when he tells us that "the army took charge of the health department of Havana when deaths were occurring at the rate of 21,252 per year. It gives it up with deaths occurring at the rate of 5720 per year. It took charge with small-pox endemic for years. It gives it up with not a single case having occurred in the city for over 18 months. It took charge with yellow fever endemic for two centuries—the relentless foe of every foreigner who came within Havana's borders, which he could not escape and from whose attack he well knew every fourth man must die. …… The army has stamped out this disease in its greatest stronghold." We cordially trust that this most pleasing picture is painted in permanent colours. But the Old World statistician seems to hanker after more information as to the rates referred to and as to whether the late war in Cuba may have had any part in accentuating the statistical contrasts.

The Grocer's Licence.

On Monday last the Home Secretary successfully moved the second reading of the Licensing Bill which was thereupon referred to the Standing Committee on Trade. We beg to congratulate him upon the progress which has been made with this measure. The Licensing Bill may not be a comprehensive or drastic piece of temperance legislation—indeed, Mr RITCHIE has himself disclaimed for his Bill any such thorough going character—but it is an honest attempt to minimise the evils of drinking, and as such deserves the support of all thinking men and women, and especially of the medical profession. How widespread and how complicated the evils of excessive drinking are is better known to medical practitioners than to any class of society The physical ills that are wrought by intemperance form the daily lessons of our hospitals, the moral effects of the same baneful habit are seen at their fullest growth in our lunatic asylums and prisons. It is consequently incumbent upon the medical profession to speak on the absolute necessity of the proper regulation of the drink traffic, although they are not called upon to vouch for all the sensational propaganda made in the teetotal interest.

During the debate on the second reading the measure received from Mr CAINE, speaking as a representative of the temperance party of the country, a qualified blessing, but several members, notably Mr HARWOOD, Mr TRITTON, and Major JAMESON, spoke in condemnatory terms of some of the clauses. Criticism of the measure centred largely around Clause 8, that which deals with grocers' licences. The present position of grocers' licences is that any person can obtain a licence of this kind as a matter of course, if he fulfils certain obvious conditions. Any tradesman against whom nothing serious can be alleged can claim from the magistrates a certificate empowering him or her to purchase a licence at the Inland Revenue Office. The local justices are not empowered or permitted to entertain the question of expediency—that is, whether their district stands in need of further facilities for procuring drink. By the new Bill the granting of these licences is placed at the free and unqualified discretion of the magistrates, no sort of claim can be made by anyone to the privilege. Mr HARWOOD, who opened the debate, objected strongly to this alteration of the law, arguing that licences when so granted would confer upon the licensees a vested interest which would add to the difficulty of compensation—a difficulty which, as all who have studied the temperance question know, still looms ahead. Major JAMESON, who believed the Bill to be "as silly as it was unnecessary," also objected to Clause 8 which he considered to place the off licence holder in a most unfair position and the effect of which he did not consider the Home Secretary to have realised. We expect that Mr RITCHIE knows the ins and outs of the matter as thoroughly as does Major JAMESON It is obvious that the new regulation may work unequally In districts where the licensed victuallers' influence is great fewer licences will be granted to grocers, but we do not fear that grocers as a class will meet with injustice any more than we fear that a local feeling against that much-abused citizen, the publican, will anywhere lead to an attempt to satisfy the drinking requirements of the community by granting licences to grocers in profusion. Mr CRIPPS, speaking also on behalf of the off-licence holder, believed that it was quite untrue to say that grocers' licences had led to the increase of intemperance A large section of the public appear to share Mr CRIPPS's view that the conditions under which liquors are sold by off-licensees are such as conduce to sobriety, while the existence of a number of businesses which have been legitimately built up under grocers' licences and about which no complaints have been made, is an argument against the abolition of the existing system which has to be reckoned with Why, Mr CRIPPS asked, should the business of any of these grocers be placed at the mercy of a bench of magistrates? The only reply is that the good of the public calls for the reform even though individual cases of hardship may occur, while it is our opinion that such cases will be so infrequent as not to be worth counting

The matter is one upon which the medical profession has a right to speak somewhat strongly We believe that we certainly endorse the views of the majority of our profession, who have given the question a thought, when we say that the proposed modification of the manner in which grocers' licences for the sale of liquor are to be obtained is advantageous to the public health and the public morality The abolition of grocers' licences has been much threatened. A quarter of a century ago we obtained in this office 900 signatures of medical men to a petition for this reform, and our movement started the feeling against off licences which has remained in force ever since. At that time we stated that, as far as we could see, the grocers licences were distinctly things that were liable to abuse. By what plea of necessity the issue of unrestricted grocers' licences could possibly be excused we were then unable to discover, and we have not been able to discover since No valid reason can be urged on the ground of general utility why the grocer should add to his proper functions a duty which makes of him virtually a disguised publican In some country districts, it may be, the provision store must serve to some extent the purposes of a house of call, but there is no absolute necessity even here for the off licence, while the discretion vested in the magistrates will meet individual cases. We have no manner of doubt that the tendency of grocers licences is to encourage secret drinking The evil influence of successive little stimulating "nips," taken when the drinker is not under observation, is well known to be nearly or quite as hurtful to the health as are the unbridled but more occasional excesses of the open drunkard. But the secret toper, who would resent the imputation of drunkenness, will avoid a professed drinking bar The grocer's licence is for such men and women—and especially for such women—a special snare. We understand, of course, that the law cannot restrain an ostensibly sober person from procuring drink if he or she chooses, but it is nevertheless quite within the province of the legislature to restrict the opportunities of those predisposed to ruinous indulgence, especially when its action can in no way interfere with public convenience. On this principle the change proposed by the new Bill is entirely justified We anticipate beneficial results from its operation—not so much, perhaps, in the case of the chronic inebriate as in that of many women to whom the off licence affords a tempting facility of descent. There appears to be no reason why the holders of grocers' licences should not receive compensation in some form if their present privilege is withdrawn. Into this part of the question, however, it is not necessary for us to enter. We may safely entrust its settlement to the consideration of the Government.

Annotations.

"Ne quid nimis."

THE GERMS OF THE SEA.

AT no particular spot has the sea been found to be free from organisms, although those isolated and recognised have proved to be harmless, consisting of actively motile rods and vibrios, cocci being less numerous. As might be expected, the number of organisms increases immensely as the shore is approached. Thus about a mile from the shore something like 4000 germs per cubic centimetre have been found, and this influence of the shore extends for four or five miles. Some hundreds of miles from land the number diminishes to 600 and at greater distances to 200 or less. Of course, the fact that algal vegetation is richest near the shore, providing a highly nourishing hunting ground for the marine organism, accounts for the myriads usually found there. Samples of sea water taken at some depth below the surface proved to contain only a few bacteria per cubic centimetre. Thus at half a mile below the surface only from eight to 12 bacteria were present There is little doubt that even should pathogenic organisms gain access to the sea, as must be the case when sewers discharge raw sewage into it, their activity must sooner or later be destroyed. The sea is remarkable from a bacteriological point of view in containing phosphorescent bacteria and it is probable that some of these are disease-producing so far, at any rate, as regards certain aquatic animals. Thus a bacterium has been successfully cultivated from the body of the luminous talitrus which is both pathogenic and luminous. This bacterium invades the abdominal cavity of this aquatic animal and all its organs with a fatal issue. During the presence of the disease the victim shines with a green light which is said to be visible nearly a dozen yards away and which persists for some hours after the demise of the animal. It is not improbable that the luminosity of other marine animals may be due to the invasion of this light- and disease-producing organism. The very beautiful phenomenon of the phosphorescence of the sea is caused by photo-bacteria in part as well as by a variety of low forms of animal life. The eerie light is in no way connected with the element phosphorus as is very commonly supposed. The cause of the phenomenon is respiratory exchange or oxidation, an aerobic function. Sea phosphorescence is never witnessed in perfectly smooth water, while the brilliancy of the light when it is observed is always greatest upon the crests of the waves or where the water is in a violent state of agitation, as in the wake of a steamer. Its occurrence, therefore, is evidence of active oxidation. Could, again, the sea be sterilised phosphorescence would cease. The presence of highly combustible matter increases the light. A very simple experiment proves this. If the flesh of a fresh haddock or herring be placed in a 3 per cent. salt solution and kept at a low temperature (from 40° to 50° F.) the liquid will rapidly develop phosphorescence which becomes quite brilliant on adding a little glycerine or sugar, or what, in other words, is respirable material. It is curious that in marine life disease and death should be associated with luminous phenomena.

EFFECTS OF STRYCHNINE ON RABBITS IN WHICH DOUBLE NEPHRECTOMY HAS BEEN PERFORMED.

IT has been well established that strychnine is eliminated from the body mainly through the kidneys. Dragendorff has shown that all the strychnine leaves the body unchanged and Kratter succeeded even with such a small medicinal dose as two milligrammes in recovering the entire quantity from the urine. If the subcutaneous administration be accomplished very slowly even more than a fatal dose may be injected without causing any characteristic effect, which has been explained on the assumption that in such a case enough strychnine is eliminated by the kidneys to prevent the accumulation in the blood of an effective dose It has been presupposed as a matter that is self evident that in an animal from which the kidneys have been removed subminimum doses will even aggregate within the blood to a poisonous dose simply because the eliminating organ is removed. This supposition has been proved not to be correct by Dr. S. J. Meltzer and Dr. W. Salant, who publish the result of their researches in the *Journal of Experimental Medicine*, vol. vi., No. 2 The title of their communication is "The Effects of Subminimum Doses of Strychnine in Nephrectomised Rabbits." Their investigations bring out the following points. 1. For a rabbit without its chief eliminating organs—the kidneys—the minimum toxic and fatal doses of strychnine are, nevertheless, not smaller than are those for the normal animals. 2. Even in a rabbit without its kidneys a single cumulative toxic dose of strychnine induces only one attack, or a few attacks, of the characteristic spasm and the animal soon recovers and shows no further effects of the strychnine. Hence a toxic dose apparently remains within the body, causing a continual effect. 3. If proper subminimum doses at proper intervals are employed "nephrectomised" rabbits can gradually receive thrice the fatal dose of strychnine without showing any reaction. Large fatal doses of the poison are apparently accumulated within the body without causing any effect. Dr. Meltzer and Dr. Salant then proceed to suggest various explanations of these facts, but, as they admit, these are only hypotheses which require further study. We consider the most plausible suggestion to be that after the removal of the kidneys the act of elimination is carried on by other organs; for instance, by the gastro-intestinal canal. The above observations are interesting from several points of view but the most practical result is the following consideration. It has been claimed by clinicians that in chronic diseases of the kidneys certain drugs, such as strychnine, should not be administered since, owing to the lessened power of elimination on the part of the kidneys, serious or even fatal accumulative results might follow According to the experiments which we have been considering, however, such a theory is incorrect and the animal body apparently possesses a mechanism capable of regulating the cumulative capacities of the blood even in the absence of the kidneys. It would be interesting to know the results of similar investigations with other drugs, such as morphine, for the fear of cumulative effect in renal disease would seem to rest at present on theoretical grounds alone.

ON THE RELATIVE PREVALENCE OF DISSEMINATED SCLEROSIS.

AN important discussion on the relative prevalence of disseminated sclerosis in the United States based upon very extensive and exact records collected by leading neurologists is published in the *Medical News* of New York of March 22nd last. In opening the discussion Professor C. L. Dana reported that he had collected the histories of 3000 private patients suffering from various forms of nervous disorders and that

) of these were instances of disseminated sclerosis. Of 600 tdoor patients seen by him at his clinic at Bellevue ospital during the past year two were probably (though not rtainly) afflicted with disseminated sclerosis. "In Bellevue ospital itself 12,000 patients were received annually and e of his assistants was continually on the watch for cases nervous diseases, yet he had not found more than one two cases of multiple sclerosis each year." From his perience he was compelled to believe that the disease was rer in the United States than in Europe, "possibly owing to e better surroundings of the masses of the people " Dr. memo Hammond from a careful examination of his case-ooks for the past 10 years found that among 3000 private atients suffering from nervous diseases 15, or 2 per cent. of e total, had disseminated sclerosis, while out of 7000 atients at his clinic 32, or 1 33 per cent., had the same ffection. Thus out of 10,000 private and hospital cases 47 ad disseminated sclerosis, a proportion of 1·5 per cent. r. Allen Starr's records of 10,056 cases at his clinic showed hat 27 had disseminated sclerosis, but in six of the latter iagnosis was recorded as doubtful. All the female patients ith disseminated sclerosis were below the age of 31 years, he youngest being 16 months old Dr Sachs stated that out f 2000 patients in his private practice 13 were undoubtedly ases of disseminated sclerosis, or 1 in 150 There were ome cases observed by him which had begun as dissemi-ated sclerosis and had in later life passed into paralysis gitans. Dr B. Onuf said that during his observations ade in hospital of nearly 600 cases of nervous diseases he ad noted eight cases of disseminated sclerosis. Dr. Edward) Fisher had during six years observed 2451 cases of ervous disorders and of these eight were examples of isseminated sclerosis Dr. Joseph Collins had in 1895 nder his care 1270 patients with nervous diseases with three f disseminated sclerosis; in 1899 the figures were 1400 nd five of disseminated sclerosis; in 1900 they were 368 patients and five of disseminated sclerosis; and in 900 they were 1470 with five examples of disseminated clerosis. Thus, of a total of 5508 patients suffering from arious nervous disorders 18 had disseminated sclerosis. Thus f a total of 33,607 patients with various nervous disorders collected from the records of Professor Dana, Dr Graeme Hammond, Dr Allen Starr, Dr Sachs, Dr Edward Fisher, and Dr Joseph Collins, 125 were examples of disseminated sclerosis, or 0·37 per cent., thus showing that the disease was comparatively rare in the United States. According to the testimony of many of the contributors to the above symposium it appeared that disseminated sclerosis was much rarer than tabes dorsalis in the United States and slightly less frequent than paralysis agitans

BACTERIOLOGY AND SEWER AIR: ITS PURIFICATION.

IN an interesting note upon this subject just published in pamphlet form Dr. J T. C. Nash, the medical officer of health of Southend-on-Sea, points out that sewer air is detrimental to health and repulsive to the sense of smell chiefly because of (1) offensive gases and (2) organic particulate matter. The offensive and prejudicial gases include sulphuretted hydrogen, sulphuretted ammonia, carburetted hydrogen, and carbon dioxide The particulate organic matter comprises such bacteria, moulds, or yeast as may happen to be present. Various investigators have shown that different samples of sewer air vary greatly in their numerical bacterial contents. The bacterial flora of sewer air are not constant in kind, the number and variety of bacteria present depending on seasonal conditions and the special environment of the sewer. It appears to be established, however, that the proportion of moulds to bacteria is greater in sewer air than in the air of the street or even of an ordinary room. Dr. Nash agrees that it is of the greatest importance that sewers and drains should be so arranged as to minimise the possibility of contamination by splashing, and he regards it as equally important that strong currents of air should be avoided or that, when that condition exists, the air issuing from a sewer should be washed before it is allowed to escape through a ventilating shaft into the street. The importance of thus arresting particulate matter is obvious from the fact that in proportion as the draughts or currents of air in a sewer are stronger or feebler the number of organisms in the sewer air will be greater or less. Sewage organisms find their way into sewer air (1) by splashing; (2) by the bursting of bubbles from putrefactive changes, and (3) by motility and the agency of moulds. Dr. Nash maintains that all that is required to secure the innocuousness of sewer air is to submit it to a thorough washing with fresh water before it is permitted to mix with the street air *viâ* the ventilating shaft. Bacteriologically the results of this simple process are satisfactory, but it would be interesting to determine whether, in spite of this fact, washed sewer air has any poisonous effect on the organism.

FACTORY GIRLS' COUNTRY HOLIDAY FUND.

WE are glad to see by the annual report of this excellent fund that both the work done by, and the resources placed at the disposal of, the fund have shown a considerable increase. The work was commenced 14 years ago, when only 39 women and girls were sent away for country holidays during the year In 1900 2680 were sent. Last year, however, the number rose to 3060 up to the middle of September, by which time the regular annual holiday exodus was over, but convalescent cases continued to be sent away until the end of the year Of this number 250 had medical certificates and stayed away for periods of three, four, or in some cases even five weeks The total number of those who have been assisted by the fund during the year amounts to 3120. There is no need to dwell upon the immense good which this fund does towards improving the health of a class whose occupation is not of the healthiest and whose social position does not enable them to live in healthy environments, but we would point out that it is not only the workers themselves who benefit by an annual holiday but the community at large, for many of these girls are engaged in the preparation of food, and it is eminently desirable that the work-people engaged in this kind of labour should not suffer from ill-health. Few, if any, funds are deserving of more support. The address of the honorary treasurer is St. Peter's Rectory, Saffron-hill.

SEVERE HÆMATURIA FROM MOVEABLE KIDNEY.

SLIGHT hæmaturia may occur in cases of moveable kidney, but such hæmaturia as was present in the following case, which is recorded in the *Boston Medical and Surgical Journal* of March 6th by Dr A. J. Cabot, is exceedingly rare. A woman, aged 43 years, was seen on April 6th, 1901. For the past few years she noticed, when tired, a dull pain in the abdomen and on several occasions observed a little blood in the urine. In December, 1900, the urine was deeply coloured with blood. In March, 1901, the urine was almost black and contained clots. She was put to bed and ergot and other hæmostatics were administered, but the hæmorrhage did not abate. On examination in April the urine was of specific gravity 1012 and alkaline; it contained between ¼ and ½ per cent of a large deposit of blood, mucus, and pus. Discomfort was experienced only during the passage of clots. On April 8th the patient was propped up in bed in a half-sitting posture. She was extremely pale and waxy in appearance, with a rapid feeble pulse The bladder was carefully examined with a sound and its posterior and lateral walls were palpated through the vagina with negative result. The right kidney was enlarged and low in the abdomen, the lower end being just above the brim of the pelvis. It could not be pushed up by moderate force and the use of more was not considered advisable. The patient's posture was thought to favour downward displacement of the kidney and to aggravate the congestion. Her extremely low condition was against operation. She was therefore laid flat in bed and the foot of the bed was raised. For 36 hours the hæmaturia seemed greater than before. But after 48 hours it diminished and a few hours later the urine was free from red colour. Three days later the foot of the bed was lowered to the floor for about four hours. Next morning hæmaturia appeared. From this time the foot of the bed was kept elevated until early in May, when the patient became tired of the position and was allowed to sit bolstered up in bed for 20 minutes daily. Hæmaturia, though far less than before, was at once noticed. From this time the hæmaturia ceased and strength was rapidly gained. On May 20th nephrorrhaphy was performed. The kidney was much smaller than at the time of the former examination—little if at all larger than normal. It could be pushed easily into its normal position. Convalescence was uneventful. In February, 1902, hæmaturia had not occurred since the operation and the patient complained only of dragging pain in the right kidney when she lay on her left side.

INFECTIOUS DISEASE IN EGYPT.

DR. ENGEL BEY, the director of statistics in the Sanitary Administration of Egypt, has published a statement in tabular form showing the incidence, with differentiation between natives of the country and Europeans, of small-pox and the so-called "typhic fevers" in Egypt during the quinquennium 1896–1900. In the following table some of Dr. Engel's most striking results have been collated:—

1896–1900.	Small-pox.		"Typhic fevers."	
	Europeans.	Natives.	Europeans.	Natives.
Deaths.				
13 Provinces	16	2386	21	2665
24 Towns (included in the above)	16	363	21	1382
8 "Gouvernorats"* ...	224	700	483	3182
Frontier Province... ..	—	360	—	—
General total...	240	3446	504	5847
Ambulances (Government).				
Admitted...	—	11581	—	8720
Died	—	2616	—	1952

* Cairo, Alexandria, Damietta, Rosetta, Port Said, Suez, Ismailia, and El Arish.

Dr. Engel's tables have been prepared with great attention to detail and afford data from which future sanitary historians will doubtless be able to extract valuable information, but it is evident that the machinery at the disposal of the Egyptian sanitary authorities does not as yet enable them to supply vital statistics referring to the great mass of the population. It is only in the large towns that the diagnosis of fatal diseases can be at all depended on and until medical practitioners of repute become far more abundant than they are at present there is but little hope of any improvement in this respect. Practically the Egyptian *fellahin* are still destitute of skilled medical aid. They enter and leave the world without any trustworthy helper to smooth the too often rugged path and fill up dangerous pitfalls. It is true that some years ago an attempt was made to introduce self-supporting dispensaries, but although the original establishments still exist they have not increased as it was hoped that they would. For many years to come—until the leaven of education has had time to work—the Egyptian cultivator will continue to trust his familiar soothsayer the barber rather than the exponent of western medicine.

HÆMORRHAGIC SMALL-POX.

AT a meeting of the Metropolitan Asylums Board on April 5th a letter was read from the Local Government Board stating that they had requested Dr. E. Klein to undertake an inquiry by bacteriological methods as to "hæmorrhagic small-pox" and asking that all necessary assistance might be afforded him in his investigation.

A PUBLIC BACTERIOLOGIST AND PATHOLOGIST FOR NOTTINGHAM.

FROM a copy of the minutes of a monthly special meeting of the Council of the City of Nottingham held on March 3rd we note that a bacteriologist and pathologist to the corporation has been appointed at a salary of £100 per annum, Dr. F. H. Jacob receiving the post. In view of the demand which in the future municipal bodies will be certain to make upon the energy, time, and skill of an official bacteriologist it is to be hoped that the remuneration will be commensurate with the services required of him. It cannot be expected that the ruling bodies of our cities and big towns should be able effectually to administer sanitary affairs without the aid of a bacteriologist and pathologist and certainly the time is at hand when all large corporations and boroughs should retain the services of an officer specially qualified in these highly-important branches of State medicine.

RECURRENT HERPES ZOSTER.

A SUPPOSED characteristic of herpes zoster is that it does not recur—that one attack confers immunity. This constitutes a distinction between true zona and other forms of herpes which frequently recur. However, a number of cases of recurrent herpes zoster have been recorded. M. Matignon has described the case of a young soldier who from childhood was subject to attacks of zona of the ophthalmic nerve, which followed one another almost without interruption three or four times a year.[1] Each attack was ushered in by fever and the general phenomena of true zona. More recently Dr. J. Grindon[2] has collected 61 cases of recurring zona. Some cases have also been reported in the *British Journal of Dermatology*. Mr. G. Pernet recorded the case of a woman who had, in December, 1891, right intercostal zona, and in December, 1892, February, 1896, and November, 1896, a group of papules, which passed into vesicles, below the right angle of the lower jaw which were preceded by neuralgic pains in the right side of the head.[3] Dr. W. Beatty has described the case of a man, aged 35 years, who had, in July, 1894, pains in the genital region which were followed by vesicles on the scrotum and between some of the toes. The condition recurred in February, 1895, May, 1895, December, 1896, and April, 1897.[4] At the meeting of the Société Médicale des Hôpitaux of Paris on March 7th M. Hirtz and M. Salomon described the following case. A man, aged 67 years, addicted to alcohol, was admitted to hospital in July, 1901, suffering from pains in, and an eruption on, the right buttocks and thighs which he had had for several days. In 1895 he had similar neuralgic pains which were followed by zona. Since then, about January or February every year, the condition had ccurred. The present attack was the first that occurred in uly. The sciatic and crural nerves were tender. On the ight buttock were tender erythematous patches covered ith vesicles, which were diagnosed as herpes zoster. ecovery took place in a fortnight. In February, 1902, ecurrence again took place. There were five patches on the ight buttock and two small ones on the left.

THE MEDICAL REGISTER.

THE Medical Register for 1902 has just appeared and we re glad to see that some of the errors to which we have ad to call attention have been removed by revision. The olume contains this year 1647 pages and a new feature s the Foreign List at the end of the book, a list hich contains at present one name only. On page 6 is given a table showing the total number of practitioners on the Register on Dec. 31st in each year. or 1900 there were 36,355 and for 1901 36,912. The otal number added by registration in 1899 was 1351; in 900, 1345; and in 1901, 1318. For practical purposes the limination of names means little, it is so small in comparison with the number of names on the Register. Yet, aken in connexion with our increasing population it may ave some significance.

AMPUTATION OF THE THIGH UNDER ANÆSTHESIA PRODUCED BY COCAINISATION OF THE SPINAL CORD.

SOME thousands of operations must have been performed nder anæsthesia produced by the subarachnoid injection of ocaine and similar drugs since Bier introduced the method n 1899. In 1900 M. Tuffier of Paris, who has perfected its echnique and extended its use, had employed it in over 200 perations without an accident.[1] But it appears to have een adopted in England only by Dr. Arnold W. W. Lea of Manchester who has performed a number of abdominal perations under spinal anæsthesia.[2] The national conservatism is influential even in medicine and in this instance seems to deserve approbation, for the advantages of the new method are not manifest and the chapter of its dangers has yet to be written. Indeed, a number of deaths has already been recorded. In the *Intercolonial Medical Journal of Australasia* Dr. Robert H. Ritchie has recorded a case of amputation of the thigh in which anæsthesia was produced by the new method. A man, aged 78 years, was admitted to hospital suffering from dyspnœa and œdema of the legs. There were a mitral systolic murmur, displacement of the cardiac apex to the left and downwards, and atheromatous arteries. The pulse at times was almost imperceptible. Under digitalis improvement took place and the œdema disappeared. Moist gangrene of the right leg occurred and extended upwards within two inches of the knee. In consequence of the heart disease general anæsthesia was thought to be impossible. Adopting the technique described in THE LANCET[3] a small quantity of a 2 per cent. sterilised solution of cocaine was injected into the skin about a quarter of an inch to the right of the middle line and midway between the third and fourth lumbar spines. A nick was made in the insensitive skin and the needle of a Luer's syringe was pushed upwards, forwards, and inwards, but the spinal canal could not be reached. The whole process was repeated on the left side and the needle was passed into the spinal canal and cerebro-spinal fluid dripped from it. After about 30 minims had escaped 30 minims of distilled water containing one-quarter of a grain of cocaine were slowly injected. The syringe and needle were left in position so that more cocaine could be injected if necessary. The left leg was repeatedly pinched. 20 minutes after the injection the patient still said that he felt a pinch distinctly and he could localise it. The possibility that the skin might, notwithstanding, be analgesic occurred to Dr. Ritchie. He made a small incision in the left calf and the patient on being asked said that he felt nothing. The incision for the anterior flap was made in the right thigh and no pain was felt, though the patient knew that the leg was being touched. The needle was withdrawn from the spinal canal, the puncture was closed with collodion, and the patient was placed on his back with a towel over his face. The operation was completed painlessly. When the femur was being divided he could hear the sawing. The femoral artery and vein were thrombosed and the cut muscles were of a brown colour. About two hours after the operation the patient complained of abdominal pain and became very excited. He had a bad night and when he took even a little water he vomited. In the morning he still complained of pain. The pulse was very irregular and much weaker. He slept all day and on waking at night took nourishment well. The wound healed by first intention Vomiting is one of the symptoms which may result from spinal injections of cocaine. Dr. Ritchie's case tends to show that by this method anæsthesia only to pain (analgesia) is produced.

THE DISTRIBUTION OF PLAGUE.

As regards Egypt, during the week ending March 30th 22 cases and 10 deaths from plague have occurred throughout all Egypt. 1 case was reported from Abousir; 4 cases were reported from Kom-el-Nour; 13 cases and 8 deaths, 3 of which occurred out of hospital, from Deshneh; 2 cases and 1 death from small villages near Benha; and 2 cases and 1 death from Korachieh. Korachieh is a village in the Santax Markaz of Gharbieh From inquiries made on the spot it is evident that the infection was carried there from cases in Tantah, and it appears that the disease broke out first in February among some Bedouins employed in the Domains Estate Instead of information being given at once to the Sanitary Department of the existence of cases of suspicious disease followed by death among these workpeople, they were dispersed and their huts were destroyed; the consequence has been that these wandering Bedouins have disseminated the disease in several small encampments about Benha. It is difficult to believe that the Domains inspector was not aware of cases of disease and death occurring among his own people, and if he was aware he has incurred, in the opinion of the Director-General of the Sanitary Department, a very grave responsibility in not having at once made the facts known. It was only on the Commissioner of the Domains noticing that certain huts which had existed near the station for several years had been removed and on making inquiries that he was informed of the reason of their removal, when he immediately informed the Sanitary Department.—As regards the Mauritius a telegram from the governor received at the Colonial Office on April 4th states that for the week ending April 3rd there had been no cases of plague.

DIPHTHERIA AND ITS TREATMENT AT COLCHESTER.

EARLY last year[1] we published an account of an outbreak of diphtheria which took place at Old Heath, Colchester, and commented on the action of the medical officer of health of the borough, Dr. G Brown, in refusing to use antitoxin for the patients at the infectious hospital—a method of treatment which he called "bowing the knee to medicinal Baal." Without assuming any right to dictate what is the proper treatment of diphtheria we pointed out that the attitude of the medical officer of health towards accepted medical teaching was very unfortunate, and some six months later, during all of which time diphtheria had been present in Colchester, the town council arrived at the same conclusion. For the members resolved unanimously that it was advisable where the antitoxin treatment had not been administered to diphtheria patients before admission to the hospital that it should be administered on admission. A report has now been made by Dr. Louis Cobbett and Dr. G. S. Graham Smith on the measures taken to check the outbreak of diphtheria in Colchester last year and from this report the value of the antitoxin treatment becomes manifest. At a special meeting of the Sanitary Committee of the town council it has been agreed to appoint a medical officer of health and public analyst to the town who shall devote his whole time to the duties of his office.

ON SOME OF THE SYMPTOMS OF CEREBRAL SYPHILIS IN REGARD TO DIAGNOSIS.

DR. WILLIAM LESZYNSKY of New York has stated in the *Medical News* of March 22nd last that the nature of the symptoms in cerebral syphilis was such as to make a practical diagnosis difficult in some cases and has supplied two illustrative instances of the same. The first case was that of a woman, aged 22 years, who denied all history of syphilis. On several occasions prior to her coming under observation she had had transitory paresis of the left arm and leg, severe headaches, vertigo, and a slight febrile temperature. On admission to hospital there were marked ptosis of the left eye and a vertical diplopia of the same eye associated with paresis of the superior rectus muscle. Vision was normal in both eyes. A slight right-sided facial paralysis was also present. In spite of the patient's denial of syphilitic infection the symptoms pointed suspiciously to cerebral syphilis and the results of treatment with mercury and iodides justified the diagnosis. The diplopia and ptosis disappeared under the above treatment. Later she developed ptosis on the right side, the levator palpebræ muscle only being affected. This also responded to anti-syphilitic treatment and disappeared in four weeks. A month later the left eye was again affected and she also suffered from headaches and temporary attacks of inability to speak (aphasia) or to swallow (dysphagia) which improved under anti-syphilitic treatment—20 grains of iodide of potassium three times a day. Dr. Leszynsky considers that the cerebral affection was a syphilitic basal meningitis in the form of patches involving the cranial nerves combined possibly with a slight degree of endarteritis. The second case was that of a man, aged 33 years, who had enjoyed good health up to August, 1899. He then developed numbness and slight local muscular twitchings on the left side of the face. In October there followed dimness of vision and diplopia of the right eye. In December the molar teeth in the right upper jaw "became so loose that they were removed with the fingers." He was the father of six children reputed to be healthy. He admitted having had a chancre many years previously but had no marked secondary symptoms. The pupils were myotic and failed to react to light or to accommodation, but vision and the funduses of the eyes were normal. Mercurial ointment and iodide of potassium were used in treatment and strychnine was also given as a tonic. At the end of two months he was much improved and disappeared from observation. He reappeared in June, 1901, suffering from almost total blindness and advanced primary optic atrophy of both eyes. The pupils were rigid and the oculo-motor nerve was paralysed in all its branches. He was now treated with strychnine without benefit and Dr. Leszynsky stated that this also was his experience with other patients suffering from cerebral syphilis in its later stages. There were no sensory disturbances in this patient and the tendo Achillis reflexes were preserved—in short, tabes dorsalis could be excluded in this case. The original diagnosis of cerebral syphilis was confirmed but owing to the advanced state of the disease there was no prospect of successful treatment.

SMALL-POX IN LONDON.

THE returns of small-pox for the past week show a decrease in the number of cases. On Saturday, April 5th, there were 46 fresh cases notified and removed; on Sunday, the 6th, there were 32 fresh cases; on Monday, the 7th, there were 57 fresh cases; on Tuesday, the 8th, there were 36 fresh cases; and on Wednesday, the 9th, there were 26 fresh cases.

LIVERPOOL SCHOOL OF TROPICAL MEDICINE.

THE Liverpool School of Tropical Medicine having urged His Majesty's Government to assist the expedition which is at present endeavouring to improve the sanitary condition of Freetown, West Africa, has received the following reply from the Colonial Office, dated March 27th, 1902. "I am directed by Mr. Secretary Chamberlain to request you to inform the committee of the Liverpool School of Tropical Medicine with reference to the letter from this office of the 7th December last that the governor of Sierra Leone has now reported on the subject of their suggestion that the Colonial Government should increase the number of the workmen lent by them to the malaria expedition which is now working in Freetown under the superintendence of Dr. Logan Taylor. Sir C. King-Harman states that he is naturally anxious to give every possible assistance to Dr. Logan Taylor in the useful and important operations which he is conducting in Freetown, but after consultation with him and with the principal medical officer he has decided that the best form in which that assistance can be given is for the Government to undertake by degrees the surface drainage of those parts of the city which are most infested by mosquitoes. In this proposal Dr. Taylor cordially concurs, recognising that such work cannot be adequately performed by his staff and that the result cannot fail, not only to relieve him of engineering responsibility, but also to effect a permanent improvement in the sanitary condition of the infested areas. Arrangements have accordingly been made for the immediate surface drainage of a swampy portion of the grass fields district in which Dr. Taylor has already operated to a considerable extent. The cost of the work is estimated at £460 and the amount has readily been voted by the Legislative Council. Mr. Chamberlain has approved of the governor's action and has sanctioned the expenditure of £460."

THE FRENCH GOVERNMENT AND LEAD-POISONING.

IN seeking to defend the hardware manufacturers who use lead for their glaze Mr. Coghill, M.P., speaking in the House of Commons on Feb. 28th, made at least one good point. He not only insisted that the cases of lead-poisoning in the Potteries had steadily fallen from 496 in 1897 to 106 last year, but remarked that in other trades there had been 1057 cases of lead-poisoning. It is certainly true that the grievance is not limited to the Potteries; for instance, house decorators are still victims to the needless employment of lead in the paint which they manipulate. Sir Charles Dilke said that in France many pottery manufacturers used no lead at all and there is no reason why this good example should not be generally followed in England, even though the better precautions now taken have reduced the frequency of saturnine symptoms among the pottery-workers. But while the English manufacturers might follow the example of the French manufacturers so far as the Potteries are concerned the British Government might also seek to imitate the French Government in regard to other trades in which lead is used. The Minister of Commerce, M. Millerand, constituted by the decree of Dec. 11th, 1900, a Commission of Industrial Hygiene, and the first work of this committee of experts was to investigate the dangers resulting from the use of lead, especially in the manufacture of paint. Further legislation was then promised on the subject and to obtain the necessary information a circular was sent to all the prefects during the month of March, 1901. The circular inquired in what communes, public establishments, and administrative offices the use of lead paint had been forbidden. As a result of this investigation it appears that in 384 communes lead paint was no longer employed. Thereupon a decree was issued on March 25th, 1901, ordering that henceforth no lead paint should be used on any premises belonging to the Ministry of Commerce and Industry of Posts and Telegraphs. This example was soon followed by other Ministers. In August the Minister of Marine decided that no lead paint should be used for any of the ships belonging to the French Navy. During the preceding month of June the Minister of Public Works adopted a similar rule for all that concerned his department. The Minister of War and (in November) the Minister of Public Instruction also issued decrees forbidding the use of lead paint in all places under their control. This is preaching by example and it has always been held that Governments should be model employers. At the same time the Government issued special instructions to all the inspectors of factories and unwholesome industries to exercise a particularly strict surveillance over the lead industries. As a consequence statistics already show that there has been a considerable decrease in the number of cases due to saturnine intoxication. In the report of Professor T. E. Thorpe and Professor T. Oliver on the employment of compounds of lead in the manufacture of pottery, presented to the Government in a blue-book dated Feb. 21st, 1899, it was pointed out (*vide* THE LANCET, April 1st, 1899, p. 919) that much of the ware supplied to the order of the various Government departments, such as the Post Office, the Office of Works, the Admiralty, the War Office, and the India Office, could be dipped in leadless glaze without detriment to its character and with no increase to its cost. We believe that the Government acted as far as was possible in accordance with this suggestion and we trust that it will maintain its energy in this very practical way.

MR. HARRY MAULE CROOKSHANK, F.R.C.S. Edin., British Controller of the Daira Sanieh Administration, has received His Majesty's Royal licence to accept and to wear the Order of the Medjidieh, Grand Cordon, which has been conferred upon him by His Highness the Khedive of Egypt, authorised by His Imperial Majesty the Sultan of Turkey, in recognition of valuable services rendered to His Highness.

THE annual dinner of the Royal Army Medical Corps will take place on Monday, June 16th, at the Whitehall Rooms of the Hôtel Métropole, London, at 7.45 P.M. The honorary secretary of the dinner is Lieutenant-Colonel E. M. Wilson, R.A.M.C., Junior Army and Navy Club, St. James's street, London, S.W.

WE regret to announce the death of Professor Hans Buchner who died at Munich on April 5th in the fifty second year of his age. Professor Buchner, who was president of the Hygienic Institute at Munich, was an able bacteriologist and rendered valuable services in the field of preventive medicine.

THE consideration of the Midwives Bill as amended by the Grand Committee has been put down for Wednesday, June 4th, when there is considerable possibility of its being

Pharmacological Notes.

PREVENTION OF PITTING IN SMALL-POX BY THE USE OF FORMALIN GELATIN OR GLUTOL.

GLUTOL is a whitish powder prepared by exposing sheets of gelatin to the vapour of formalin. This substance is the subject of an article by Mr. John Moir[1] wherein its therapeutic uses are described. In practice, by the solvent action of the living tissue to which this preparation is applied, the gelatin is dissolved and thus liberates the antiseptic factor, the formalin. The value of formalin as an antiseptic in cases of surgical tuberculosis has been recognised during recent years to such an extent that it is largely replacing iodoform glycerin with its objectionable odour. The solvent action of glutol is facilitated by the addition of lard or of soft paraffin. The following conditions are mentioned in which its use is beneficial: stomatitis (by means of a syringe), suppurative conditions of the mouth, gums, and tongue, carcinoma, epithelioma, tuberculosis, severe burns; and severe chronic ulcers. But it is of special interest to note the recommendation that glutol should be employed, mixed with soft paraffin in the proportion of 1 to 4 or 1 to 8, as a preventive of severe pitting and deep scars from small pox, this proportion has been found useful in tuberculosis, in carcinomatous and epitheliomatous cases as well as in severe burns. The addition of a bland emollient vehicle such as soft paraffin is in all cases preferable. With a protective covering of gauze glutol is aseptic. It is found that, generally speaking, the use of glutol prevents the development of exuberant granulations and scars, it is useful in preventing the irritation, scratching, excessive swelling, and inflammation of the eyelids and of the mouth, especially as it is entirely harmless as an application in the mouth, even when swallowed in considerable quantity. Dr. Gustave Daniel of the City Hospital, Bielefeld, found in 1899 that glutol caused improvement in cases of many epithelial diseases, warts, cancroid growths, and in sycosis vulgaris, his observations were confirmed by Dr. Kranefuss, physician in-chief at that hospital. They found the treatment absolutely trustworthy, although it took more time than most of the remedies, but it was easy to handle, did not cause any special pain, and left no scar. The value of glutol as a preparation for the treatment of wounds has been dealt with by Dr. Heinrich Mohr,[2] by Dr. Heinrich Lobb of Mannheim,[3] and by Dr. Robert Maguire.[4]

MEDICINAL TREATMENT OF TUBERCULOSIS.

Dr. Hugo Winternitz, physician at the Royal Medical University Hospital in Halle on Saale, in an article on the treatment of tuberculosis in hospitals[5] states that hygienic dietetic therapeutics alone are not sufficient for the treatment of pulmonary diseases. With regard to medicinal treatment even Gerhard, in spite of his former expression that "medicinal treatment of tuberculosis has been a complete failure," is now in favour of special medicinal therapeutics as far as the employment of drugs is concerned. Of these creasote alone has held its own. The use of this drug, however, is sometimes attended by decrease of appetite, disturbed digestion, and diarrhœa. As a result various substitutes for creasote have been introduced—notably, guaiacol and thiocol and their preparations. Guaiacol, the principal constituent of beechwood creasote, only reduced these difficulties without removing them. Various combinations of guaiacol and of creasote with carbonic acid were then introduced—viz., creasotum carbonicum (creasotal), guaiacolum carbonicum (duotal), creasotum valerianicum (eosote), the ester of valerianic acid and guaiacol (geosote), and, finally, thiocol, a sulphuric combination of guaiacol (ortho guaiacol-sulphate of potassium). Thiocol contains 52 per cent. of guaiacol and is a white micro-crystalline powder, unalterable by exposure to air, of a slightly bitter but not disagreeable taste and perfectly inodorous, it is soluble in four parts of cold water and has no corrosive effect even in concentrated solutions, a circumstance which may account for the fact that it does not irritate the digestive organs.

---

[1] The Therapist, Feb. 15th, 1902, p. [illegible].

[2] The Therapist, July 15th and August 15th, 1901, pp. 145 and [illegible].

[3] Ibid., August, 1901, p. 178.

[4] Ibid., p. 179.

[5] Ibid., Feb. 15th, 1902, translated from the Deutsche Aertze Zeitung, [illegible] Jan. 1st, 1902.

Dr. Winternitz gives details of eight out of 16 cases in which thiocol has been used, enabling an opinion to be formed as to the value of this drug. He concludes that thiocol has advantages over creasote or guaiacol, being palatable and free from disagreeable secondary effects. With the exception of complicated cases the appetite improved, the weight of the body increased, nocturnal sweats were reduced, and catarrhal symptoms, when present, decreased. In advanced cases, however, the relief of the cough is only gained by the use of morphine (or its substitutes) the *ultimum refugium*. Codeine and dionine have a sedative effect and a favourable influence on expectoration; they reduce the irritability of the air-passages without limiting the respiratory functions, as experimentally shown by Dr. Winternitz.[6] Dionine is prescribed in doses of from 0·03 gramme, preferably in solution; thus, dionine 0·6 gramme, water 100·0 grammes; one teaspoonful in the evening. Thiocol is conveniently prescribed in the form of a syrup, thus: Thiocol, 10 grammes; water, 40 grammes; fluid extract of orange, five grammes; and simple syrup, 95 grammes. Dose, from three to four teaspoonfuls daily, corresponding to about from one gramme to one and a half grammes of thiocol per diem. (In England the tincture of orange might be prescribed in place of the fluid extract recommended by Dr. Winternitz.) Thiocol may also be given in powders or in tablets in doses of from 0·5 to 1·0 gramme three times a day.

THE NEW BILL ON LAUNDRIES.

(FROM A SPECIAL CORRESPONDENT.)

THE Earl of Lytton has revived the hopes of the much-neglected laundry-workers by obtaining the second reading of his Factory and Workshop Act (1901) Amendment Bill. If legislation for the protection of labour is justifiable it is doubly justifiable in regard to laundry-workers. In this case not only are the workers themselves concerned but it is a matter which intimately affects the entire public. The articles washed are those which are worn nearest to the skin, and if laundries are not well managed they become an active means of spreading disease. Therefore, inspection is more necessary in regard to this business than in regard to many other industries. Yet it is precisely the laundries that were left out of the Factory and Workshop Act which was passed last year. This omission, it will be remembered, was due to the opposition of the Irish Members. They objected to the inspection of laundries established by convents and other religious institutions. It was feared that if this matter was fought out either the session would have to be prolonged or the Bill would have to be abandoned. The Government therefore sacrificed the laundries so as to save the rest of the Bill. Now, however, the question of the laundries is brought forward on its own merits independently of all other questions, and the Bill introduced by Lord Lytton is a considerable improvement on the laundry clauses that were withdrawn from the Bill of 1901. Mr. Ritchie's Bill of 1901 did not include small laundries and it only dealt with the larger laundries where steam-power machinery is employed. The first clause of Lord Lytton's Bill includes the small laundries and assimilates them to workshops while the larger laundries are qualified as factories. From the point of view of the public the small laundries are more dangerous than the large. They are generally in dwelling-houses where cases of small-pox, scarlet fever, &c., may be concealed and may contaminate the linen after it has been washed. From the workers' point of view the employment of children and the working of excessive hours can be more readily concealed in a private dwelling than in a separate building which by reason of its size and the number of persons employed is more like a factory. The second clause of Lord Lytton's Bill applies the same limits to the hours of labour for children and women as exist in other trades, but the clause allows 60 days' overtime in the year, and this is more than is granted for the packing of perishable articles. Unless it be a matter of tactics just to get the Bill through there is *no* sufficient reason for such exceptional leniency. With the employment of machinery especially it is possible to calculate with mathematical precision exactly the amount of washing that can be done, so there is no need to promise what some exceptional circumstance may render it difficult to fulfil. It is not like the packing of fruit or the curing of fish which depends upon varying factors, such as the weather and the uncertainties of fishing.

The third clause deals with the phase of the question that gives rise to the greatest opposition. A portion—we are pleased to recognise that it is not the whole but only a portion—of the Roman Catholic community is opposed to the inspection of the laundries connected with religious institutions. A great deal of this opposition is sentimental and political and is due to the fear that Catholic and Irish institutions will be overrun by Protestant and Saxon inspectors and that men will obtain a right of entry into convents inhabited solely by women. Though such objections appeal strongly to passion and prejudice they are in themselves very feeble. There is no desire to inspect convents but only these portions of the buildings which have been converted into laundries. Nor is it necessary that the inspector should be a man and a Protestant; there is nothing in the Bill to prevent the appointment of a woman and a Roman Catholic. The fact is that under the broad mantle of religion unfair competition has been organised against commercial enterprise. These so-called charities have proved to be very remunerative concerns. According to the registrar of charities 71 homes have earned in the course of a year £30,670. Five or six of them make more than £1000 annually out of their laundry work. The Penitentiary Home of Edinburgh realises £5000 a year and the work of 15 crippled and feeble inmates of St. Mary's Home at Gloucester yields no less than £580. And this is a growing business, for Lord Lytton explained that the home at Clewer which competes with private enterprise for the washing for Eton College made £1400 in 1899 and £1723 in 1901. But in so far as such institutions are connected with the Church of England the Bishop of Winchester and the Bishop of Rochester expressed in the House of Lords their willingness to see them brought under the Factory and Workshop Regulations. Surely the restraints which the claims of humanity and the laws of hygiene have imposed on commercial enterprise should be more than welcome in religious houses. Those who act in the name of religion, more than any other section of the community, should scorn the protection of secrecy and should court the fullest publicity so as to vindicate the righteousness of their motives.

The necessity of energetic and effective control over laundries is clearly shown by the various reports of His Majesty's inspectors of factories and workshops. In many laundries work is continued from 8 in the morning till 11 at night for four days. Then there is 10 hours' work on the fifth day and none on the sixth and seventh. That this can be avoided is proved by the example of Lancashire and Yorkshire where the women will not, and do not, work longer in the laundries than they do in the textile factories. The crowding of the work of the week into a few days is the cause of many dents or of ill-health. The whole of the work is done st ing. The same grievance exists in other trades but nc the same extent. The difference is due to the excessive h worked during some days of the week and perhaps to relaxing effect of the very damp and overheated atmosp Then in regard to accidents H.M.'s Inspector's Repor 1900, p. 383, says: "Accustomed to the conditions of life work among ordinary factory workers, nothing is so stri to the inspector as the spectacle of numbers of young from 14 years of age and upwards all legally employe 10 or 11 o'clock at night in the ordinary factory labou tending machinery. Passing at night from one facto another and finding the young calender feeders empl in their mechanical task of 'feeding' the large ste heated power-driven ironing-rollers with the damp l to be ironed (a cloud of steam rising as each 'pi is passing through) it is impossible not to specu on the effect of the work and the hours of these yo girls. One can only feel surprised that accidents not more numerous when one realises that the slightest c lessness or inattention may result in the fingers or hand b drawn between the hot cylinders and when one consi how easily such inattention may arise in the case of the c tired young workers. In few, if any other industry, are daily working hours so long. Working and standing in steamy hot atmosphere of a calender-room from 8 A.M. 9 or 10 P.M. all the week, with the exception of one day an arduous strain on the young constitution."

Clearly it is more important to limit the hours of w done in the course of a day than the total amount d during the whole week. Young girls especially should not be allowed to reach that state of exhaustion which prevents the alertness that is necessary to prevent accidents and which predisposes them to constitutional disease Nor should such evils, while abolished in commercial undertakings, be allowed to continue in convents. One of the inspectors relates that he received complaints of a religious community where women had been kept at laundry work for 19 hours in one day If these institutions are established, as is stated in many cases, for the purpose of redeeming women from a life of vice, is it likely that they will attract many penitents when they impose 19 hours at the washtub as an alternative to the freedom of the streets? But if it were known that such abuses would henceforth be impossible, that the women penitents would not be made to work harder than factory operatives, there would surely ensue more numerous conversions Some religious institutions claim that the laundry work which they do is only an aid to self support, but it appears that in some cases the profits from washing are 15 times larger than those derived from any other source. The charity has degenerated into a regular business and has therefore no right to exemption from the laws that protect the workers in other commercial enterprises This is admitted by a great number of Roman Catholics themselves and it is not impossible that, if all the facts were better known, the Church of Rome as well as the Church of England would welcome the proposed legislation

DEGREES FOR LONDON MEDICAL STUDENTS

THE following petition from Licentiates of the Royal College of Physicians of London and Members of the Royal College of Surgeons of England has been presented to the governing bodies of the two Colleges

To the Presidents Fellows &c., of the Royal College of Physicians London and the Royal College of Surgeons, England

Whereas it is becoming increasingly important to medical practitioners to have a right to call and style themselves Dr"

Whereas your petitioners find that in the practice of their profession through their inability to call and style themselves "Dr" they do labour under very great disadvantages in comparison with the graduates of the Universities of Scotland Ireland and the Provinces of England and also in comparison with the licentiates of certain of the examining bodies:

And, whereas your petitioners feel that they have gone through a course of professional study, which is as prolonged and thorough as that laid down for the above graduates and licentiates and have passed examinations which are equal in severity and strictness to those through which the above graduates and licentiates have passed:

And, whereas your petitioners feel that it is to the interest of the whole medical profession that the Royal College of Physicians, London, and the Royal College of Surgeons England, should continue to attract students to the metropolitan schools;

And, whereas your petitioners believe that the Royal Colleges can only continue to attract students to the London schools by removing the above-mentioned disabilities

Your petitioners would therefore pray that the Royal Colleges would:—

(1) Approach the governing body of the New University of London or some other British university with a view to obtain for the Licentiates and Members the privilege to offer themselves as candidates for the final examination for a degree in medicine or

(2) That the Royal Colleges would take some other and independent step to remove the disabilities under which their petitioners labour

And your petitioners would ever pray, &c.

We have every sympathy with the petitioners in their desire to place the diplomates of the two Royal Colleges on the same footing with regard to a degree as the graduates of Scottish, Irish, and some provincial English universities. In THE LANCET of Nov 23rd, 1901, p 1425, we referred at length to a somewhat, if not exactly, similar circular which it was proposed to present to the Royal Colleges. We also gave a short *résumé* of what has been done from time to time ever since 1885 and we cannot see that anything more remains which can be done, unless, indeed, by the foundation of a new university Still, perseverance has before now overcome apparently insuperable obstacles, *ἐς Τροίαν πειρώμενοι ἦνθον Ἀχαιοί*, as the old woman said in Theocritus, and a grievance is not the worse for being kept prominently before the public Degrees can at present, in these islands, be obtained from only two sources—namely, a university and His Grace the Archbishop of Canterbury[1] (The Archbishop's power is practically in abeyance, for in the case of medicine it is never exercised.) The petitioners' first line of attack is to petition the Royal Colleges to approach the newly constituted University of London or some other British university with a view to obtain for diplomates of the Royal Colleges the privilege of offering themselves as candidates for the final examination for a degree in medicine. In case of this method of attack failing the Royal Colleges are requested to take some other step to remove the disabilities under which their petitioners labour As regards the first proposal we doubt whether the Royal Colleges will accede to the request and even if they do it is more than doubtful whether the University of London or any other university will consent to any relaxation of the tests at present surrounding their degrees This may seem a hard saying but it is true and the truth is often bitter

The only way out of the difficulty which appears to us to be at all feasible is the foundation of a new university in London. This plan was put forward as a solution of the problem in the report of the delegates appointed by the two Royal Colleges to consider the question at issue, and the report will be found at length in THE LANCET of Dec. 18th, 1886, p 1194 The next step after the issue of this report was an application to the Crown for power to be given to the Colleges to grant degrees This application was referred to the Royal Commission on Higher Education in London and on April 28th, 1889, was unanimously rejected

If, then, the petitioners should fail to induce the Colleges to apply to the University of London and the other British universities, or in case they do apply and the universities refuse to grant their request, it appears to us that the "some other and independent step" has already been taken without advancing matters.

ASYLUM REPORTS.

London County Asylum, Hanwell (Report for the year ending March 31st, 1901)—The average number of patients resident during the year was 2516 and comprised 902 males and 1614 females. The admissions during the year amounted to 548, including 259 males and 289 females. Of these, 442—viz, 207 males and 235 females—were first admissions. Dr R. R. Alexander, the medical superintendent, states in his report that "as to the forms of mental disease [among the admissions] general paralysis was accountable for 15 per cent. of the males and nearly 4 per cent. of the females, as compared with 14 per cent. and 4 per cent. respectively in 1899, and 14 per cent and 3 per cent. in 1898.' General paralysis among the male admissions had fallen somewhat irregularly from 27 per cent in 1894 to 15 per cent. in 1900, and in that time the female cases of general paralysis had also fallen considerably but the proportion of the sexes (three or four men to one woman affected with general paralysis) remained unaltered "It would at last really seem,' adds Dr Alexander, "as if general paralysis is relaxing its hold on that part of the community whence we obtain our patients And our experience is by no means singular" As regards the causes of insanity in the admissions it appeared that alcoholic intemperance accounted for 25 per cent. of the male admissions as compared with 20 per cent. in 1899 and 16 per cent. in 1898. Among the females 13 per cent. were due to the same cause. Previous attacks of insanity had occurred in 21 per cent. of the males and 22 per cent. of the females admitted, while a hereditary tendency to insanity could be traced in 26 per cent of the males and 21 per cent. of the females. "We have to deplore the admission of a good many feeble senile patients who are brought to the asylum practically to pass therein the few days of life remaining to them, and one would fain hope before long that workhouse infirmaries will be provided with the means of properly treating and indefinitely retaining such cases" The number of patients discharged as recovered during the year was 218, including 81 males and 137 females, or 8·6 per cent of the average number resident. The deaths during the year amounted to 232—viz., 103 males and 129 females, or 9 2 per cent. as calculated on the same basis Of the deaths two were due to Bright's disease four to epilepsy, six to colitis, 11 to cancer 11 to cerebral hæmorrhage, 14 to cerebral softening 20 to bronchitis, 21 to senile decay, 22 to pulmonary phthisis 25 to cardiac disease, 32 to pneumonia, 38 to general paralysis of the insane, and the rest to other causes

---

[1] Phillimore: Ecclesiastical Law, 1895, p 1505.

The Commissioners in Lunacy did not make a visit during the year under review. The asylum sub-committee states in its report that a sum of £453 was spent in laundry improvements, that the farms and fields were in a good state of cultivation, and that the live stock was healthy. The sum of £354 was spent in additions and alterations and the sum of £8975 in repairs during the year.

St. Andrew's Hospital for Mental Diseases, Northampton (Annual Report for 1901).—This is a hospital for the reception of insane patients of the middle and upper classes, the rates of payment being 42*s.* and 25*s.* per week respectively for first and second class accommodation. The average number of patients resident during the year was 402, comprising 191 males and 211 females. The admissions during the year amounted to 107—viz., 44 males and 63 females. Mr. Joseph Bayley, the medical superintendent, states in his report that "the hospital and all the houses have been quite full during the greater part of the year. 158 patients have had the advantage of a change of air and scene at our new house, Bryn-y-Neuadd Hall, North Wales. This is a much larger number than we have ever been able to send before. The place is much liked, both by patients and by their friends who have been there." During the year 41 patients were discharged as recovered—viz., six males and 31 females, or 10·2 per cent. of the average number resident. The deaths during the year amounted to 12—viz., nine males and three females, or 2 9 per cent. as calculated on the same basis. Of the deaths one each was due to cardiac disease, aneurysm, apoplexy, and bronchitis, two were due to senile decay, three to general paralysis of the insane, and the rest to other causes. One patient while out on trial at her own home committed suicide with a revolver. "The hospital and the houses belonging to it have been free from infectious disease, with the exception of the house in North Wales where a servant fell ill with typhoid fever. ......She was placed under treatment in one of the detached houses and recovered." The committee of management has recently sanctioned a larger outlay for entertainments to enable the engagement of theatrical companies from London; so far this has been a great success and the patients are much pleased with it. The Commissioners in Lunacy state in their report that they visited the institution twice during the year and found on each occasion that the patients were comfortable, that the building was in admirable order, that the day rooms and dormitories were airy, bright, comfortable, and scrupulously clean, and that the case-books were well and intelligently kept. The branch establishment in North Wales was also visited and everything was found in the best possible order.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8662 births and 5010 deaths were registered during the week ending April 5th. The annual rate of mortality in these towns, which had been 17·6 and 18·2 per 1000 in the two preceding weeks, declined again to 17·6 per 1000 last week. In London the death-rate was 17·9 per 1000, while it averaged 17·4 in the 75 other large towns. The lowest death-rates in these towns were 9·3 in Bournemouth, 9 9 in York, 10·5 in East Ham, 10·6 in Leyton, 11 0 in Hornsey, 11·2 in West Hartlepool, 11·3 in Bootle, and 11·7 in Tottenham; the highest rates were 21·5 in Liverpool and in Leeds, 21·8 in Middlesbrough, 22·0 in Tynemouth, 22·2 in Merthyr Tydfil, 22·9 in Wigan, 26·5 in Plymouth, and 29·2 in Burnley. The 5010 deaths in these towns last week included 572 which were referred to the principal zymotic diseases, against 553 and 602 in the two preceding weeks; of these 572 deaths 171 resulted from measles, 128 from whooping-cough, 77 from small-pox, 72 from diphtheria, 54 from diarrhœa, 42 from scarlet fever, and 28 from "fever" (principally enteric). No death from any of these diseases was registered last week in Hornsey, Hastings, Brighton, Bournemouth, Ipswich, Coventry, Grimsby, Bootle, Rotherham, West Hartlepool, or Tynemouth; while the highest zymotic death-rates were recorded in Croydon, Willesden, Handsworth, Aston Manor, Birkenhead, Burnley, Barrow-in-Furness, South Shields, and Rhondda. The greatest proportional mortality from measles occurred in Willesden, Burnley, Barrow-in-Furness, Huddersfield, Stockton-on-Tees, and Merthyr Tydfil; from scarlet fever in St. Helens; from diphtheria in Croydon, Swansea, and Rhondda; from whooping-cough in Handsworth, Aston Manor, Wallasey, and Barrow-in-Furness; from "fever" in Handsworth, Aston Manor, and Birkenhead; and from diphtheria in Walsall. The 77 deaths from small-pox registered last week included 54 of persons belonging to London, 10 to West Ham, four to East Ham, two each to Croydon, Tottenham, and Leeds, and one each to Leyton, Walthamstow, and Southampton. There were 1522 cases of small-pox under treatment in the Metropolitan Asylums hospitals on Saturday, April 5th, against 1542, 1567, and 1526 at the end of the three preceding weeks; 376 new cases were admitted during the week, against 450, 449, and 389 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had declined from 3137 to 2147 on the 14 preceding Saturdays, had further decreased to 2126 at the end of last week; 228 new cases were admitted during the week, against 266, 258, and 250 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had declined from 885 to 360 in the six preceding weeks, further decreased last week to 317 and were 75 below the corrected average number. The causes of 69, or 1·4 per cent., of the deaths in the 76 large towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bristol, Nottingham, Bolton, Salford, Cardiff, and 38 other smaller towns. The largest proportions of uncertified deaths were registered in Northampton, Burton-on-Trent, Liverpool, St. Helen's, Preston, Halifax, Stockton-on-Tees, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 23·7 and 20·3 per 1000 in the two preceding weeks, rose again to 21·3 per 1000 during the week ending April 5th, and was 3·7 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 16·0 in Paisley and 17·2 in Perth to 23·4 in Dundee and 26·5 in Greenock. The 687 deaths in these towns included 15 which were referred to diarrhœa, 14 to whooping-cough, 11 to measles, eight to scarlet fever, five to diphtheria, four to "fever," and two to small-pox. In all 59 deaths resulted from these principal zymotic diseases last week against 85, 83, and 59 in the three preceding weeks. These 59 deaths were equal to an annual rate of 1·8 per 1000, which was slightly below the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of diarrhœa, which had been 25 and 22 in the two preceding weeks, further declined last week to 15, of which nine were registered in Glasgow, three in Dundee, and two in Aberdeen. The deaths from whooping-cough, which had been 23, 28, and 13 in the three preceding weeks, rose again to 14 last week and included seven in Glasgow, two in Edinburgh, and two in Aberdeen. The fatal cases of measles, which had been 14, 11, and 14 in the three preceding weeks, declined again last week to 11, of which five occurred in Glasgow, and five in Dundee. The deaths from scarlet fever, which had been eight, five, and three in the three preceding weeks rose again to eight last week, and included four in Greenock and three in Glasgow. The fatal cases of diphtheria, which had been four and six in the two preceding weeks, declined again last week to five, of which three were registered in Glasgow. The deaths referred to "fever," which had been four, four, and one in the three preceding weeks, rose again to four last week, and included two in Glasgow, where the two fatal cases of small-pox also occurred. The deaths from diseases of the respiratory organs, in these towns, which had been 189, 217, and 173 in the three preceding weeks, further declined last week to 160, but were 10 in excess of the number in the corresponding period of last year. The causes of 29, or more than 4 per cent, of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 20·6, 22·4, and 27·5 per 1000 in the three preceding weeks, declined again to 26 8 per 1000 during the week ending April 5th. During the past four weeks the death-rate averaged 24·3 per 1000, the rates during the same period being 19·3 in London and 18·7 in Edinburgh. The 195 deaths of

* Including membranous croup

persons belonging to Dublin registered during the week under notice showed a decline of five from the number in the preceding week, and included six which were referred to the principal zymotic diseases, against eight, six, and seven in the three preceding weeks; of these, two resulted from diphtheria, and one each from measles, scarlet fever, "fever," and diarrhœa. These six deaths were equal to an annual rate of 0.8 per 1000, the zymotic death-rates during the same period being 2·4 in London and 0·8 in Edinburgh. The 195 deaths in Dublin last week included 28 of children under one year of age and 51 of persons aged upwards of 60 years; the deaths of infants showed a slight decline from the number recorded in the preceding week, while those of elderly persons were slightly in excess. Nine inquest cases and four death from violence were registered, and 76, or more than a third, of the deaths occurred in public institutions. The causes of 12, or more than 6 per cent., of the deaths registered in Dublin last week were not certified.

VITAL STATISTICS OF LONDON DURING MARCH, 1902.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in each of the cities and boroughs in the county of London. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 11·9 per 1000 of the population, estimated at 4,579,107 persons in the middle of the year. In the three preceding months the rates had been 10·6, 11·4, and 11·4 per 1000 respectively. The rates were considerably below the average in Kensington, Hammersmith, Chelsea, the City of Westminster, and Hampstead, while they showed the largest excess in Hackney, Shoreditch, Bethnal Green, Stepney, and Poplar. During the four weeks ending March 29th the number of small-pox cases notified showed a further increase as compared with recent months; the greatest proportional prevalence of this disease was recorded in Holborn, Finsbury, Shoreditch, Bethnal Green, Stepney, Poplar, and Woolwich. The Metropolitan Asylums hospitals contained 1526 small-pox patients at the end of March, against 666, 1135, and 1309 at the end of the three preceding months; the weekly admissions averaged 461, against 173, 297, and 390 in the three preceding months. The prevalence of scarlet fever last month showed a slight increase over that recorded during February; among the various metropolitan boroughs this disease was proportionally most prevalent in St. Pancras, Stoke Newington, Bethnal Green, Battersea, Wandsworth, Camberwell, Deptford, and Lewisham. The number of scarlet fever patients under treatment in the Metropolitan Asylums hospitals, which had been 3080, 2501, and 2250 at the end of the three preceding months, had further declined to 2113 on Saturday, March 29th; the weekly admissions averaged 206, against 297, 266, and 234 in the three preceding months. The prevalence of diphtheria last month was slightly greater than in the preceding month; this disease was proportionally most prevalent in St. Pancras, Islington, Hackney, the City of London, Wandsworth, Camberwell, and Lewisham. There were 1123 diphtheria patients under treatment in the Metropolitan Asylums hospitals at the end of March, against 1369, 1231, and 1154 at the end of the three preceding months; the weekly admissions averaged 156, against 160, 167, and 154 in the three preceding months. Enteric fever was considerably less prevalent during March than in either of the two preceding months; among the various metropolitan boroughs enteric fever was proportionally most prevalent in Paddington, Stepney, Finsbury, Wandsworth, Camberwell, and Deptford. The number of enteric fever patients under treatment in the Metropolitan Asylums hospitals, which had been 195, 128, and 142 at the end of the three preceding months, had declined again to 121 at the end of March; the weekly admissions averaged 17, against 21, 18, and 22 in the three preceding months. Erysipelas was proportionally most prevalent in Paddington, St. Marylebone, Hackney, Holborn, and Southwark. The 16 cases of puerperal fever notified during the month included three in Lambeth, two in Kensington, and two in Wandsworth.

The mortality statistics in the table relate to the deaths of persons actually belonging to the *various* metropolitan boroughs in which the deceased persons had previously resided. During the four weeks ending March 29th the deaths of 7166 persons belonging to London were registered, equal to an annual rate of 20·4 per 1000, against 18·8, 18·3, and 25·9 per 1000 in the three preceding months. The lowest death-rates last month in the various metropolitan boroughs were 13·1 in Lewisham, 13·4 in Hampstead, 16·1 Stoke Newington, 16·4 in Woolwich, and 16·9 in Wandsworth; the highest rates were 24·1 in Southwark, 24·8 in Finsbury, 25·0 in St. Marylebone, 26·1 in Holborn, and 26·6 in Shoreditch. The 7166 deaths from all causes included 275 from small-pox, 267 from measles, 38 from scarlet fever, 96 from diphtheria, 199 from whooping-cough, 26 from enteric fever, and 45 from diarrhœa; in all, 946 deaths were referred to these principal zymotic diseases, equal to an annual rate of 2·7 per 1000. The lowest death-rates last month from these diseases were 0·7 in Chelsea, 0·9 in Hampstead, 1·4 in Lambeth, 1·5 in Hammersmith and in the City of London, and 1·6 in the City of Westminster; the highest rates were 4 1 in Bethnal Green, 4·9 in St. Marylebone and in Stepney, and 5·1 in Fulham. The 275 fatal cases of small-pox showed a further increase over the numbers in recent months; the greatest proportional mortality from this disease occurred in Holborn, Shoreditch, Bethnal Green, Stepney, Poplar, Southwark, Deptford, and Woolwich. The 267 deaths from measles were slightly in excess of the average number in the corresponding periods of the 10 preceding years; among the various metropolitan boroughs this disease was proportionally most fatal in Paddington, Kensington, Fulham, St. Marylebone, Finsbury, Shoreditch, and Greenwich. The 38 fatal cases of scarlet fever showed a decline of 13 from the corrected average number; the greatest proportional mortality from this disease was recorded in St. Pancras, Islington, Holborn, Southwark, and Bermondsey. The 96 deaths from diphtheria were 40 per cent. below the average number in the corresponding periods of the 10 preceding years. Among the various metropolitan boroughs this disease was proportionally most fatal in St. Pancras, Islington, Hackney, Finsbury, and Camberwell. The 199 fatal cases of whooping-cough showed a decline of 54 from the average number in the corresponding periods of the 10 preceding years; the greatest proportional mortality from this disease occurred in Stoke Newington, Shoreditch, Bethnal Green, Bermondsey, and Lewisham. The 26 deaths referred to enteric fever were slightly below the corrected average number; among the various metropolitan boroughs this disease was proportionally most fatal in Hampstead, Stepney, Poplar, Wandsworth, and Lewisham The 45 fatal cases of diarrhœa also showed a slight decline from the average number; the highest death-rates from this disease were recorded in Fulham, Stepney, Poplar, Southwark, Battersea, Deptford, and Woolwich. In conclusion, it may be stated that the aggregate mortality in London last month from these principal zymotic diseases was more than 6 per cent. above the average.

Infant mortality in London during March, measured by the proportion of deaths among children under one year of age to registered births, was equal to 135 per 1000. The lowest rates of infant mortality were recorded in the City of Westminster, Hampstead, Battersea, Wandsworth, Lewisham, and Woolwich; and the highest rates in Fulham, Stoke Newington, Shoreditch, Southwark, and Deptford.

THE SERVICES.

ARMY MEDICAL SERVICE.

THE undermentioned Colonels to be Surgeon-Generals:—William F. Burnett, Royal Army Medical Corps, vice J. Jameson, C.B., placed on retired pay. Dated June 1st, 1901. Edmond Townsend, C.B., C.M.G., Royal Army Medical Corps, vice W. A. Catherwood, deceased. Dated Sept. 25th, 1901. William H. McNamara, C.B., C.M.G., Royal Army Medical Corps, vice H. S. Muir, C.B., placed on the supernumerary list. Dated Oct. 4th, 1901. Sir Thomas J. Gallwey, K.C.M.G., C.B., Royal Army Medical Corps, vice T. F. O'Dwyer, placed on retired pay. Dated Dec. 26th, 1901.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel G. T. Trewman is appointed to the Home District for duty. Lieutenant-Colonel W. A. Parker, Reserve of Officers, proceeds to Exeter for duty, in medical charge of the 11th Regimental District, and Lieutenant-Colonel W. B. Slaughter joins for general duty in the Southern District.

Imperial Yeomanry.

Buckinghamshire (Royal Bucks Hussars): Surgeon-Captain Leonard Arthur Bidwell, from Middlesex Garrison Artillery (Volunteers), to be Surgeon-Captain. Yorkshire Hussars (Princess of Wales's Own): Walter Henry Cheetham to be Surgeon-Lieutenant.

Volunteer Corps.

Rifle: 1st Volunteer Battalion the Prince Albert's (Somersetshire Light Infantry): Surgeon-Lieutenant R. G. Worger to be Surgeon-Captain. 2nd Volunteer Battalion the Manchester Regiment: John Alfred Knowles Renshaw to be Surgeon-Lieutenant.

Volunteer Infantry Brigade.

Durham Light Infantry. Surgeon-Lieutenant-Colonel T. A. McCullagh, 2nd Volunteer Battalion the Durham Light Infantry, to be Brigade-Surgeon-Lieutenant-Colonel whilst holding the appointment of Senior Medical Officer to the Brigade.

Highland Light Infantry: Surgeon-Lieutenant-Colonel D. Cowie, 5th (Glasgow Highland) Volunteer Battalion the Highland Light Infantry, to be Brigade-Surgeon-Lieutenant-Colonel whilst holding the appointment of Senior Medical Officer to the Brigade.

2nd London: Surgeon-Major W. D. Waterhouse, 1st Tower Hamlets Volunteer Rifle Corps, to be Brigade-Surgeon-Lieutenant-Colonel whilst holding the appointment of Senior Medical Officer to the Brigade.

East Surrey: Surgeon-Lieutenant-Colonel W. Gandy, 2nd Volunteer Battalion the East Surrey Regiment, to be Brigade-Surgeon-Lieutenant-Colonel whilst holding the appointment of Senior Medical Officer to the Brigade

West Surrey: Surgeon-Major F. R. Russell, 2nd Volunteer Battalion the Queen's (Royal West Surrey Regiment), to be Brigade-Surgeon-Lieutenant-Colonel whilst holding the appointment of Senior Medical Officer to the Brigade.

Army Medical Reserve of Officers.

Surgeon-Captain J. Adams to be Surgeon-Major.

South African War Notes.

Civil Surgeon A. L. Hoops is reported severely wounded during the repulse of Delarey at Boschbult, Kleinhardts River, on March 31st.

Lieutenant W. S. Crosthwait, R.A.M.C., has been discharged from hospital for duty.

Lieutenant A. O. B. Wroughton, R.A.M.C., and Civil Surgeons Roberts, Wethered, Kornohan, Cornwall, and Maunsell are on passage home from South Africa.

Affairs in South Africa.

Several events of a more or less stirring character have taken place in South Africa of late. In the first place, there have been several encounters and a good deal of severe fighting—with Delarey's force in particular. Both sides have possibly been desirous by their renewed activity in the field of influencing the course of the pending peace preliminaries. Be this as it may it is calculated that the total number of the Boer forces still amounts to 8000 Considering the Boer tactics and the extent of territory over which the operations extend the "wearing down" process and the use of columns in sweeping the country seem to be the only methods on which any reliance can be placed. It is very uncertain whether any satisfactory peace proposals on the side of Mr. Schalk Burger and his party will arise out of the Boer conferences. The only way to peace is apparently through an active prosecution of war on our part. We know, and have known all along, little or nothing trustworthy about the losses on the part of the Boers, but these must have been heavy of late. The total reduction of the military forces on the British side through war in South Africa has, according to the War Office return of April 7th, been as follows The deaths of officers and men in South Africa have amounted to 1020 officers and 20,031 non-commissioned officers and men; the missing and prisoners number 136; and the invalids sent home who have died or have left the service as unfit number over 5700 officers and men. The total reduction in officers, non-commissioned officers, and men from all causes amounts to 26,954. Although there is still much enteric fever it is, on the whole, less prevalent than it was and the sickness is attributed more to "other causes" than was the case some time ago. In proportion as the facts about the concentration camps have become better known and as observations gathered on the spot by capable and impartial persons have been published so has a great change taken place in public opinion in regard to this subject; reasonable people have come to recognise that all that was possible at the time was done. The institution of refugee camps for the unprotected wives and families of the Boers left on the veldt was a vastly responsible and difficult undertaking which probably no other nation under similar circumstances would have attempted. The organisation and arrangements of these camps were necessarily bad and incomplete at first. This was inevitable, seeing that they were a perfectly new institution in war, but these difficulties were eventually overcome and they are now well organised under medical officials from India accustomed to the work of famine relief in that country.

Deaths in the Services.

Surgeon-Captain George Ramsay, I.M.S., Residency surgeon, Baghdad, on March 24th, at Baghdad, Turkish Arabia, in his thirty-fourth year. He served with the Chitral Expedition (medal and clasp) and in 1894 he was appointed to Guntok, in Sikkim, as medical officer. In 1896 he was appointed as acting Residency surgeon at Baghdad and assistant political agent.

Surgeon-General James Champion Penny (retired), at his residence, in Nevern-square, London, S.W., on April 3rd. The deceased officer was 72 years of age. He took part in the relief of Lucknow and Cawnpore during the Indian Mutiny, receiving the medal and clasp. He was a student of St. George's Hospital, where he distinguished himself, and he graduated at London University, of which he was an M.D. He then became medical tutor at Neville Hall, Newcastle-on-Tyne, in connexion with the University of Durham and the Newcastle Medical School, a post which he held for some little time before entering the Indian Medical Service. He served for a long time in India where he made many friends and was well known and greatly respected.

Inspector-General Hugh Martin Macpherson, I.M.S. (Bengal), retired, at his residence in Arlington-street, London, S.W., on April 4th, in his eighty-second year.

Queen Alexandra's Imperial Nursing Service.

We understand that the Nursing Board of Queen Alexandra's Imperial Military Nursing Service will be constituted as follows:—President, Her Majesty the Queen; Vice-President, the Countess Roberts; Chairman, the Director-General, Army Medical Service, or in his absence the Deputy Director-General; two members of the Advisory Board, Sir F. Treves, K.C.V.O., C.B., and Major W. G. Macpherson, Royal Army Medical Corps; matron-in-chief, Miss S. Brown (temporary); two matrons of civil hospitals, Miss Gordon and Miss Monk; representative of the India Office, to be named later by the Secretary of State for India, and two members to be nominated by Her Majesty, the Viscountess Downe, and the Hon. Sydney Holland.

Naval Medical Supplemental Fund.

At the quarterly meeting of the Directors of the Naval Medical Supplemental Fund, held on April 8th, when Sir J. N. Dick, K.C.B., presided, the sum of £71 was distributed among the several applicants.

An Improved Phonograph.—As mentioned in The Lancet of Jan. 11th, 1902, p. 131, Mr. Stroh's new violin was shown and played upon not many days previously at the Royal Institution. On April 7th it was shown by Mr. Stroh at an evening meeting held in the Camera Club, Charing Cross-road, but it was not played on, as about two hours were agreeably spent in the reproduction of music and recitations by Mr Stroh's phonograph. A special feature of this instrument is the diaphragm which is about two and a half inches in diameter and consists of a stripped celluloid photographic film having a large part of its surface covered by a centrally placed cone carrying the usual rounded sapphire point at its apex. This cone is made of stiff writing paper and has an extremely obtuse angle. About a dozen instrumental pieces were given, several of them being performances by a London regimental band, including selections from *Lohengrin*, *Cavalleria Rusticana*, *Faust*, and *Tannhäuser*. The phonograph was well heard in all parts of a large room; its enunciation was loud, clear, and almost free from nasal quality. The respective sounds of wood and stringed instruments playing together could be easily distinguished and individual qualities in the voices both of vocalists and reciters were well preserved.

Correspondence.

"Audi alteram partem."

THE REORGANISATION OF THE ARMY MEDICAL SERVICE.

To the Editors of THE LANCET.

SIRS,—The promulgation of the Royal Warrant is a definite step in the proposed scheme of army medical reform and comprises that section of it which requires Royal assent, the remaining sections coming within the range of action of the Secretary of State for War and other officials to be subsequently embodied in regulations, instructions, orders, &c. It requires but a brief comparison of the Warrant with the War Office scheme as previously set forth to recognise how large and important are the complementary details left untouched by it; indeed, the Warrant, mainly relating to pay and its governing conditions and rank, may be regarded rather as a bid for candidates than as an exponent of the intentions or the authorities towards placing the future medical staff on an efficient basis for the large and important duties—professional, sanitary, and military—entrusted to it during peace and war. And yet this Warrant will probably be relied on by the young medical man towards deciding him in the adoption or otherwise of the army as a fit sphere for his professional career, as possible of giving him a fair field for his livelihood and for his life's work and a fair opportunity for obtaining for his talents and professional and scientific acquirements and labours such recognition as he is entitled to and such as would probably fall to his lot did his life's work lie in the civil sphere. How far this Warrant will operate in favour of the service remains to be seen, but it requires to be read, and should be read, by all aspirants in conjunction with the details which are to follow and to supplement it; sufficient, however, is forthcoming to show clearly that the authorities in improving the pay of some of the respective ranks and giving additional and charge pay and other advantages under certain specified conditions require a very decided *quid pro quo* in the shape of up-to-date attainments so far as these can be gauged by examinations, inspections, reports, or otherwise, should these tests be efficiently and strictly carried out. That these features will tend not only to curtail the number of aspirants to an army career but also to maintain a fair average professional status throughout the service of the future may be granted, yet the inducements held out towards personal professional and scientific progress seem decidedly insufficient for the wants of the case. To illustrate my meaning let one note the high position given to "distinguished service in the field"—a possible incident only in the career of the individual and limited both in range of action and in future utility—towards promotion and special reward as compared to that given to "distinction in original investigation or research,"—open to all independent of time and place and generally valuable irrespective of such exceptional circumstance as war—which is relegated in the Warrant to a footnote, a "Secretary of State's instruction." It is, of course, possible that such professional and scientific advance may find recognition under the principle of "selection" for promotion to the rank of lieutenant-colonel and upwards, yet it requires to be noted that so far the grounds on which this principle is to operate are not stated to embrace these features, while the division of agency for the right execution of the principle as embodied in the scheme, annulling all assessable personal responsibility for the result, leaves much to be desired in respect to this important function. However, speaking generally, it will probably be allowed that the governing features of this Warrant are of a character to improve the future professional status of the Army Medical Service, and their outcome in practice must be left for time and experience to determine.

But my main object is not so much to direct attention to what is officially on record, or to the other hardly less important details still wanted to complete the scheme, and to which you, Sirs, refer in the leading article of THE LANCET of April 5th, p. 977, as to point out that, all said, Warrants, regulations, instructions, and orders are but means to an end, which in themselves necessary and important are insufficient to place our future medical service on the ambitious height desired by the Secretary of State for War—*secundus nulli;* they require not only to be honestly and thoroughly carried out but also to have full and sufficient provision and scope for right and efficient action—a proper environment. That the authorities are now full of good intentions and the country also may be granted, but the more important question is, what will the army conditions be when the distress of the present war has ceased to operate and when the present excitants to action have been succeeded by the recoil of weariness and possible apathy—how far the environment will be such as to foster and to mature this scheme which needs for its full and complete development the combined good-will and honest support of so many army sections, placed as the medical service is among the other constituents of the military organisation? That the service as proposed will be very costly no one can doubt, and this feature will require a strong and sympathetic War Minister to obtain for it the necessary pecuniary supplies; that it will need the full acquiescence and firm support of the army generally from the Commander-in-Chief downwards in order to give it a fair field to work in will be easily grasped by those who know from practical experience in the past what the opposite conditions are capable of as antagonising agencies to any scheme subject to the disfavour of its higher powers; that it will need a Director-General professionally no less than militarily competent, fully alive to the requirements of the times as bearing on the many-sided character of his department, capable of initiating and fostering a professional and scientific *esprit de corps* and zealous in maintaining its rightful position among the other army sections, is no less apparent. And in view of these essentials, when one recalls the noble purposes of the commission following the Crimean disasters, the high hopes entertained of its practical outcome—the Magna Charta of the department as it was then regarded—whereby "men of high professional qualifications were at once attracted to the service," and contrasts the state of affairs brought about by some 30 years of official indifference and neglect and army opposition, leading practically to a shunning of the army by the profession, and rightly so, the thought arises in the mind whether the past may not repeat itself and this new Warrant and scheme go the way of the outcome of the labours of Mr. Sydney Herbert and what safeguard there may be capable of acting as a preventative to any such disastrous repetition. The well-being of the future medical service will need the concurrence of the Treasury, the War Office including the Commander-in-Chief and the army generally, the medical head-quarter staff and the profession, and it will be necessary for one and all to act in unison to bring the service up to the standard required by the times and to maintain it at that level. The *personnel* of the first three factors is changeable, the individuals come and go, and there is no guarantee that the necessary continuity of interest and action will be maintained; the profession and the general public may agitate to redress grievances and defects, yet it is not redress but prevention which must be sought for. What is required is some agency which, while recognising the value and necessity of a competent medical service to safeguard army efficiency, shall be generally and continuously operative and sufficiently powerful to influence the higher orders, and such a force, it seems to me, could be found in a sound public opinion in the military body alive from experience to the necessity of high professional ability for its well-being, individually and collectively. What I take it the army wants in its medical staff is, besides ordinary social, intellectual, and military qualities in its members, a good professional standard which can be relied on in times of sickness and injury to do all that medical and surgical knowledge suggest and to give sound advice, sanitary or otherwise, on all points touching the health and efficiency of the troops; and what is further required is the development of a right feeling of comradeship between the medical and other army sections, based on mutual respect, esteem, friendship, and interest, and which shall recognise in the medical service the friend and professional adviser of the army as a whole. From such a standpoint and on such a foundation the medical service might rest secure far beyond what Warrants and regulations can by themselves effect, and without such a basis of permanent stability one seeks in vain for the essentials necessary to maintain it in an active and progressive condition at all times—now and in the future. This necessary environment is non-existent and has to be generated, and what will go far towards producing it is, as an initial step, getting the right stamp of medical man to join the service and, as a subsequent step, maintaining the body at a high professional and scientific level. Whether the present scheme as fully developed will tend to bring about those desiderata remains to be determined, but certainly the Warrant itself seems to fall short of the latter requisite. What the medical service requires to recognise is that its true *raison d'être* is professional and scientific in the major degree and in a minor degree military, and that it is on this basis, and this basis alone, that it can claim the assent of the whole army confraternity

I am, Sirs, yours faithfully,
FRANCIS H WELCH,
Surgeon-Colonel (retired) Medical Staff
Brandram-road, Lee, April 5th, 1902.

150 ARTHROTOMIES

To the Editors of THE LANCET

SIRS,—Some six years have elapsed since I first invited attention to the value of arthrotomy with drainage in cases of traumatic hæmarthrosis and of traumatic arthritis and a year later I was induced to apply the same treatment to joint effusion in cases of rheumatic fever and gonorrhœal arthritis. The results have proved satisfactory beyond anticipation even in the latter maladies and I have been enabled from time to time to publish cases in THE LANCET and other journals showing the rapid and permanent effect which arthrotomy has on a rheumatic or gonorrhœal knee

In all I have operated on 29 cases of blennorrhagic arthritis, 27 were restored to the normal condition and two were uncured, in the latter fibrous ankylosis had existed prior to operation. I do not intend again to break down old adhesions in this disease for if a successful result is to be hoped for operation must be performed before the joint structures become pickled in the septic and plastic products of gonorrhœal infection. As far as my experience goes I am not cognisant of any other method of treatment which gives such uniformly good results.

88 arthrotomies have been performed for the malady commonly known as acute rheumatism, but which I have considered necessary to designate acute infective arthritis and cellulitis, for, as previously stated, the word "rheumatism" does not convey any explanation of the condition. In my first paper on this subject I maintained that it was an infective process, the germ or toxin gaining admission to the body *viâ* the tonsil or other microbial trap-door, and recently bacteriological investigations tend to support a conclusion which I formed five years ago from the use of a knife In this series 76 joints were restored to their normal state, all being acute or subacute cases with effusion, in the remaining 12 the disease had existed for months, and in some instances for years, before admission to hospital. Arthrotomy, breaking down old adhesions, irrigation and drainage seemed to give relief, but in none could *restitutio ad integrum* be said to have taken place. In my experience the knees, ankles and wrists, in the order mentioned, bear the brunt of the attack, and I find that if the infective fluid is promptly removed by incision and free drainage is provided the constitutional symptoms promptly subside, the rapidity of cure being in direct ratio to the duration of the toxæmia. No difference of opinion exists nowadays as to the universal canon, "*Ubi pus ibi evacua*," and if the word "*pus*" signified all septic fluid there would be no necessity for this paper, but the inane part of the business is that unless the liquid presents one of the colours of the rainbow it is not considered worthy of surgical intervention. Yet the absurdity is most obviously apparent when one considers that in some of the most virulent cases of septic peritonitis we not infrequently find only a small quantity of dirty water, the same kind of flaky, tinted serum that I constantly remove from rheumatic joints, accompanied with symptoms of general toxæmia, at times almost pyæmic in character I consider it a duty to drain these joints and by so doing to remove hotbeds of infection where the morbid material is incubated and prepared for distribution to the cardiac valves, the pericardium, and to other articulations. In order effectively to combat the insidious vagaries of this dreadful affection I strongly advocate removal of infective fluid from the joints as soon as it is detected. By this means cardiac and general metastasis can be avoided and the more I see of this disease the more convinced do I become that it has much in common with pyæmia and gonorrhœal arthritis

15 arthrotomies have been performed for traumatic hæmarthrosis Since 1896 I have operated on every case of hæmarthrosis which I have diagnosed with one result—prompt cure At times the diagnosis is not easy, particularly when patients do not seek hospital treatment for some days after injury, and it has occurred to me on three occasions when operating as I supposed for traumatic serous effusion to find instead a collection of blood and clots It is unnecessary to repeat my ideas elsewhere expressed as to the advantages derived from early operation in these cases further than to mention that in five minutes a surgeon can effect more than can be obtained by massage, &c., in five weeks (possibly months).

18 arthrotomies have been performed for acute traumatic arthritis, all the patients being cured. It has been my practice for some time past to resort to early operation in these cases, and generally, if rest, ice, and gentle massage do not bring about appreciable diminution of the effusion in one week, arthrotomy is performed, the joint is irrigated with warm salt lotion, and a drainage-tube is inserted for three days, by this means true physiological rest is provided for the injured structures and as a consequence rapid and permanent cure follows.

On only one occasion had I reason for any alarm on the ground of sepsis which happily was dispelled in 24 hours by a large stab counter opening and repeated irrigation with warm mercurial lotion, 1 in 1000 At the same time I wish to inculcate on any surgeon about to undertake an arthrotomy to make as certain of his cleanliness as if he were going to operate for the removal of an ovarian cyst. One amputation would be a huge discount on even 99 cures.—I am, Sirs yours faithfully,

JOHN O CONOR, M.A., M D Dub,
Senior Medical Officer British Hospital, Buenos Ayres

THE MIDWIVES BILL

To the Editors of THE LANCET.

SIRS,—It must be admitted that the dominant position in the healing art of the general practitioner must be jealously guarded from unreasonable encroachment by unauthorised claimants to popular favour For what purpose do the Medical Acts exist if not to protect the public from ignorant and unreliable practitioners? The course of study for students in the medical profession is now extended from three years to five or six in order to obtain high class practitioners in every department—men who are fully instructed in the many details and technicalities of a learned profession. We have thus an additional claim upon our legislators that they should defend the public from the *vox clamantis* of charlatans who trumpet their wares at every corner of the street. A midwife, if she understands her business, will, too often, like "the importunate widow," take very good care that every woman attended in her confinement shall hand her name on to some more wealthy neighbour or friend. Such persuasive garrulity a general practitioner with any self respect would scorn to imitate.

In order to place the practice of midwifery before the public in its proper and judicial aspect we must not fail to recognise that it is as much a branch of the medical art as any other branch of medicine—take, for example, orthopædic surgery, dermatology, or gynæcology Any one of these might be, and has been, practised under certain circumstances by intelligent women without any particular harm accruing to the patient, but this is no argument for registering the illegal practice of such women. The student of obstetrics knows well how many months and years of study are required before he can become proficient in the science and art of midwifery, acquiring that dexterity which is so needful an equipment for sudden emergencies. To delegate the same powers to a woman who at best is only qualified to attend a case of natural and normal labour requires careful consideration, so that she may promptly pass on the responsibility of a difficult case to a duly-qualified practitioner and may know when to do so with advantage. We are confronted with one of the most difficult problems connected with the registration of midwives—viz., who is there that can define the meaning of "natural labour"? If, for example we take only the question of a natural presentation, what a multiplicity of dangers and complications threaten the viability of the child and the safe deliverance of the mother in such cases. The village midwife engaged with a critical case suddenly discovers at midnight that she requires the aid of a duly-qualified practitioner. Who is there that will go to the town through sleet and snow to obtain the services of the expert? When he is found, is it right to expect that he will accept attendance upon the wife of a labouring man with no prospect of being recouped for his services? What will happen to the woman during the waiting hours?

It must, however, be admitted that these are not new difficulties. History records the fact that in all ages and in all countries woman has been called to the aid of her suffering sister in this her great peril. It is a modern refinement of cultivated society to obtain the services of a skilled practitioner with ready and ample resources for every emergency. No one will dispute the fact that this has been a great gain to the human race. The mortality statistics of the child-bearing period give ample evidence of the fact that human life has been preserved and suffering diminished by the skilful attendance of obstetric practitioners upon women during their confinements. We cannot, even if we so desired it, ostracise the midwife. She is a factor to be reckoned with. Over 200,000 women in this country are attended by midwives annually. Their services are secured by preference by the women themselves, and all that we demand as scientific practitioners is that this practice shall be regulated by such parliamentary measures as will protect the lives of those who are entrusted to their care. Therefore, when the Obstetrical Society comes in and offers to provide a qualifying examination for midwives so that they may practise their profession with some amount of skill and discretion, such humanitarian efforts for the amelioration of the lot of the necessitous poor must claim our acknowledgment. A woman thus brought into close association with the methods of practice adopted by the profession, and duly warned of the dangers which she is certain to encounter in her practice, should be the more ready to send and ask for the help of a neighbouring practitioner when any difficulty arises.

What we need to impress upon the Government is that if it determines to give a legal status to the practising midwife it becomes us to demand attention to the corresponding obligation—viz., that the safe delivery of a woman is only one part, and that a small part, of her obligations. The defence of the puerperal woman from the encroachment of septic germs, and the safe conduct of her case through the many shoals and dangers of the puerperal period can only be effectually guarded against by knowledge which the expert has acquired after years of study and research in the medical school. Hence the importance—I would say the necessity—of linking on every registered midwife with a qualified practitioner residing in the district where she works to whom she can have direct access in cases of difficulty or emergency.

I cannot understand why some general practitioners should object to the registration of midwives. Some kind of registration must precede any official regulation of their practice. Countless thousands of poor women have to submit to the ministration of these disqualified obstetricians on account of their poverty, yet the vast majority of them would gladly receive the services of an expert working upon trained scientific principles acquired after many years of hospital study. The manly fortitude and ready talent for sudden and grave emergencies, so characteristic of our race, will always make the man-midwife a *persona grata* with women of all grades. I do not think we need fear the ghost of supersession. We have got rid of Betsy Gamp from our hospitals. We have flooded our towns with trained nurses who have proved most valuable aids to our practice and useful watch-dogs over the foibles and fancies of our patients. Why stop short at the midwife? Are we not all advocates of antiseptic midwifery? Do we not agree that the puerperal state and the needful manipulation of lacerated tissues constitute a most fruitful source of germ infection by ignorant women? Are the lay public, many of whom are eagerly supporting the claims of the Midwives Society, aware of the dangers of employing women whose hands and clothing must be loaded with bacteria and septic germs as they hurry from house to house in densely populated neighbourhoods? Surely the remedy for all this loose and dangerous practice of self-constituted midwives is to place them under the authority of the medical officers of health, or of the local practitioner who should receive their reports, train them in habits of cleanliness and antiseptic treatment, and thus guard them from carrying infection from house to house, and also inhibit them from "attending cases of abnormal labour" except in consultation with a registered practitioner. Let us convince the House of Commons and the philanthropic public that in resisting this measure we are not contending for the right of guarding our own interests, but of safeguarding the public in populous centres from the ignorant and dangerous practice of unauthorised midwifery. A registered midwife with hospital training should prove a most valuable aid to our hard-working practitioners by reporting all cases of labour to the proper authorities and of the existence of epidemic disease in the houses they visit, receiving a small fee for so doing from the local authority.

Let it be clearly understood by the lay public that the medical profession do not object to the registration of midwives as such. The better instructed a woman becomes for the duties of her calling so much the better for the health of the community. But is it possible by an Act of Parliament to make a midwife an obstetric practitioner? However clever and skilful she may be it is impossible to qualify her for attending any but ordinary or natural labours under a certificate of three months' instruction in midwifery. As soon as the child is delivered and the placenta removed the woman passes into a puerperal condition the gravity of which can only be measured by a practitioner who has spent years in the study of obstetrics and gynæcology The avenues for septic infection are numerous and intricate The midwife may be skilful in the administration of an antiseptic douche but she cannot possibly know the source whence the bacterial infection has been communicated. She cannot explore with speculum and other appliances the manifold involutions of the vaginal or uterine membrane. She has no proper qualifications for testing the pulse or the temperature, or for examining the vital organs. The life of the woman depends upon prompt and skilful treatment of these emergencies. The statistics of lying-in hospitals show unmistakably that in confinements attended by duly-qualified medical men and women the mortality is much less than in those attended by midwives. If the Houses of Parliament determine to register duly-qualified midwives, well and good; but they must go one step further and provide medical attendance for that numerous class of cases that go wrong because the midwife is not competent to prescribe for, or treat, the complications of the puerperal state.

The only way to protect the public from incompetent and meddlesome midwives is to require the woman to be in direct communication with a local practitioner or medical officer of health for the treatment of all emergencies. This might be effected by requiring a notification certificate to be sent to the duly constituted authority of all cases attended by a midwife, with an additional request for assistance in case of emergency. The registrar or the relieving officer to give the required warrant for the attendance of the medical officer of the district when the emergency is communicated to him.

I am, Sirs, yours faithfully,

FREDERICK CHURCHILL,
Formerly Resident Medical Officer to the General Lying-in Hospital, Lambeth.

Cranley-gardens, S.W., April 4th, 1902.

THE TREATMENT OF SUPERFLUOUS HAIRS BY ELECTROLYSIS.

To the Editors of THE LANCET.

SIRS,—It need hardly be remarked that the removal of superfluous hairs from the face is of the utmost possible importance from a feminine point of view. The only really efficient method of obtaining that result is by electrolysis, notwithstanding all that has been written about the x rays—or, rather, exposure to the focus-tube—as a means of depilation. It is not too much to say that the presence of hair on the upper lip and chin may mar the whole life prospects of a woman. The condition, moreover, is extremely common—far more than is generally suspected even by observant medical men—as the feminine instinct prompts women to hide the defect as much as possible by the use of depilatories and by shaving. Notwithstanding these facts the operation of electrolysis has been allowed to drift away from the medical profession, in whose control it should most assuredly have remained, into the hands of unqualified persons.

The use of the focus-tube for epilation is not one that has yet stood the test of prolonged experience. The hairs admittedly return again and again, but it is contended that in the long run their power of reproduction is overcome and no more hairs appear On the other hand, unless the exposure to the x ray tube is conducted by the most skilled and cautious operator the results may be disastrous. The writer has seen and recorded[1] cases in which obstinate ulcers of many months' duration have been thus produced on the chin It seems more than likely that any unqualified person applying the x ray tube in this manner and with such results would be liable to incur heavy damages in a court of law Electrolysis, also, is essentially a surgical procedure, and as such should never have been allowed to pass out of the hands of the medical profession Some day it is possible that the General Medical Council may recognise its duty to the profession in protecting its interests in this and other directions by pressing the amendment of the Medical Acts upon the attention of Parliament.

The combined method of depilation—namely, by use of the focus-tube to loosen the hairs and subsequent cauterisation of the empty follicle by the electrolysis needle—is, unfortunately, applicable only in cases where the growth of hair is coarse and scattered. That condition excludes at once the great majority of cases of hirsuties in which the growth is diffuse, thick, and coarse, or downy In the latter class electrolysis is the only available means of scientific treatment. Depilatories merely palliate the evil for the time being, while in the long run they cause the growth of the hairs to be redoubled.

The objections to electrolysis are well known. It is tedious and painful, but both these obstacles are surmountable with a little determination on the part of the patient. There can be little doubt that all, or almost all, conceivable cases of hirsuties can be overcome in time if the resolution of the patient and the patience of the operator be sufficiently strong A great deal of harm is done to the credit of the operation by the claims of unqualified persons who, as usual, seek to prove too much. They say, for instance, that the pain is trifling, that the destruction of the hair is certain, and that no mark is left On the other hand, after some considerable experience the present writer is able to affirm that it is impossible to remove deep coarse hairs without a fair amount of pain and that some slight scarring must necessarily result. The truth of the latter statement will at once be apparent to all medical readers As to recurrence, it is admitted by all medical writers upon electrolysis that re-growth of the hairs takes place in a fair percentage of the follicles operated upon, say, from 15 to 20 or 30 per cent. That result must necessarily follow from the varying direction of the hair follicle and bulb which runs now this way and now that and is sometimes bent on itself like the letter C A second electrolysis of the young recurring hair is then likely to end in the complete destruction of the bulb. With the aid of a small battery and a most simple apparatus it is within the power of any medical practitioner to perform this little operation which would thereby be kept in the hands of the profession.

I am, Sirs, yours faithfully,

DAVID WALSH, M.D Edin.

A CASE OF GANGRENE OF BOTH NIPPLES IN THE PUERPERIUM

To the Editors of THE LANCET

SIRS,—With reference to Dr Ralph Vincent's interesting notes in THE LANCET of April 5th, p. 962, I think that there is no doubt as to orthoform being the cause of both rash and gangrene. Several instances of the latter complication have been recorded Professor Dubreuilh of Bordeaux has recently dealt with the subject of orthoform eruptions, including gangrene, in *La Presse Médicale*, No 40, 1901, p 233, also abstract in the *British Journal of Dermatology*, vol xiii., 1901, p. 277 I am, Sirs yours faithfully,

GEORGE PERNET

Upper Gloucester place, N W April 7th, 1902.

THE STUDY OF THE HISTORY OF MEDICINE

To the Editors of THE LANCET

SIRS,—Under the above heading there is a letter in THE LANCET of March 8th, p 696, from Mr G C Peachey begging that the profession in England shall now begin to take some interest in the study of medical history Though this study is not part of the curriculum of medical students it is essentially a post-graduate subject, and I am glad to say that I have introduced many English colleagues to the interesting works of Withington and of Puschmann, which latter has been so well translated into English by Dr E. H. Hare. In this historical country it has always seemed to me a necessity that Egyptian students should know something of the medical history of their own country, and therefore I usually preface my course of lectures on medicine by telling them something of the medical history of Egypt. I suppose it is fair to say that the earliest known triumphs of the healing art were celebrated in Egypt, and everyone knows that the famous schools of Heliopolis and Memphis, where physicians taught side by side with priests, were within a few miles of modern Cairo Herodotus in the fifth century B C marvelled at the number of physicians in Egypt, and a little later Ptolemy I. allowed human dissection to take place for the first time in the world's history in Alexandria.

In the second century of our era Galen studied in Alexandria before he settled to practise in Rome, but about A.D 500 the Christian doctors were driven out of Alexandria and settled in Persia where they taught many Christians and the Arabs who for the next 500 years represented the highest form of medicine and spread their knowledge over half the then known world, including Egypt, where they started hospitals, lunatic asylums, and a university Later, in the eleventh and twelfth centuries, the torch of medical learning was again carried to Italy by the Arabs, and Arabic medicine was soon transmitted *viâ* Bologna and Padua to England and Germany During the last 20 years English and German physicians have been restoring to Cairo and Alexandria the modern fruits of that knowledge which was for so many years almost a monopoly in Egypt. I sincerely hope that one of the many existing British societies may feel inclined to popularise within our profession the history of medical teaching I am, Sirs, yours faithfully,

F M SANDWITH

Cairo, March 29th, 1902.

ADMINISTRATION OF STRYCHNINE FOR CARDIAC FAILURE DURING AND AFTER SEVERE OPERATIONS

To the Editors of THE LANCET

SIRS —Anyone who is in the habit of reading current medical literature can hardly fail to notice the frequency with which strychnine is administered for cardiac failure taking place during or after a severe operation. The usual method apparently is to give five minims of the liquor either by the mouth or subcutaneously, to repeat this dose once or twice, with the utmost caution, at varying intervals, and then to stop its administration, apparently from fear of poisoning the patient. The following instances are in marked contrast to this method.

1. A woman, aged 39 years, was anæsthetised by me with nitrous oxide and ether for the operation of pylorectomy The operation lasted two and a quarter hours, the anæsthesia being maintained throughout with ether administered from a Clover inhaler without the bag Three-quarters of an hour from the commencement saline solution was injected intravenously to the amount of three pints, to which were added one ounce of brandy and 20 minims of liquor strychninæ. Halfway through the operation the patient's condition became so bad, the respiration being shallow and the pulse very weak (its rate about 160) that it was very doubtful whether she would be alive at its completion. During the last hour I injected 30 minims of liquor strychninæ in doses of 10 minims into the substance of the greater pectoral muscles, producing decided improvement in the volume of the pulse. Oxygen was also administered towards the close of the operation when the peritoneal cavity was filled with hot saline solution. The patient lived. During the last hour and a half 50 minims of liquor strychninæ were given without producing the slightest twitching

2. I have published a case[1] in which, after I had performed colostomy of the transverse colon for pelvic cancer in a woman, aged 64 years the patient was kept alive by doses of liquor strychninæ (five minims) every four hours, at first sub cutem and later per os with the important addition of extra doses of strychnine every time the pulse began to

---

[1] The Röntgen Rays in Medical Work. Third edition. London 1902 p 214

[1] Brit Med Jour, April 28th 1900, p 1024

intermit, which occurred several times during the first 48 hours. This patient had 1865 minims of the liquor in 64 days without the slightest symptom of poisoning but with marked benefit to her heart.

3. I have recently anæsthetised a man, aged 30 years, suffering from tuberculous peritonitis for which cœliotomy was performed, the lungs being also affected. Chloroform was given in preference to ether because of the lung affection. The anæsthesia lasted one hour, at the end of which his pulse became very feeble, almost running, the rate being about 190. I injected 20 minims of liquor strychninæ into the substance of the left pectoralis major; in about seven minutes the pulse improved considerably in strength with its rate reduced to 120 No symptoms of poisoning resulted.

4. Mr. B. G. A. Moynihan[2] has recorded a case of double primary amputation, on the right side at the hip-joint, on the left side in the middle of the thigh, in which 45 minims of liquor strychninæ were given hypodermically in three-quarters of an hour, producing good stimulation but no symptom of poisoning.

From the above and other similar cases it is evident that strychnine may be administered to combat cardiac failure in doses much larger and more frequent than is usually considered safe. Patients in a state of collapse stand these larger doses well, their administration causing marked improvement in the pulse, usually without any twitching. Even where some twitching occurs it is of comparatively little importance. It is of little use to inject strychnine under the skin of an extremity in a pulseless patient, the circulation of the part in such a case being almost non-existent. It is quite possible by making frequently repeated subcutaneous injections of strychnine into the extremity of a pulseless patient to cause convulsions, because, if the patient's circulation improves—as, for instance, after intravenous injection of saline solution—the strychnine which has accumulated in the subcutaneous tissues is rapidly absorbed owing to the improved circulation, the patient getting within a short space of time the whole amount of the hypodermic injections. The ideal method of introducing strychnine into the general circulation is to give it with the saline solution when intravenous infusion is being performed. I have had no experience of injecting undiluted liquor strychninæ into a vein. A useful place for injection is the pectoralis major, the drug being injected into the substance of the muscle. This site has the additional advantage that if artificial respiration is being performed the drug is massaged into the circulation. It is not enough to order a patient with a feeble intermittent heart so much strychnine at regular intervals—for instance, every four hours; his heart may stop long before the time for the next dose comes round. For my more severe operation cases I am in the habit of instructing the nurse to inject, in addition to the four-hourly dose, five minims of the liquor into the substance of the pectoralis major every time the pulse becomes weak and to repeat this dose of five minims every 10 minutes until either the pulse improves or general, not slight local, twitching occurs. I prefer a twitching to a pulseless patient —from the first condition recovery is probable, from the second it is not.

am, Sirs, yours faithfully,

Plymouth, April 7th. C. Hamilton Whiteford.

SOUTH AFRICAN CIVIL SURGEONS' DINNER.

To the Editors of The Lancet.

Sirs,—The second annual dinner of South African civil surgeons will be held at the Hotel Cecil on Monday, June 9th, at 7.30 p.m. Sir Frederick Treves, K.C.V.O., will take the chair. The price of tickets will be half a guinea. On account of the difficulty of obtaining the names and addresses of civil surgeons who have returned from the war, we hope that all who intend to be present will communicate with us as soon as possible and urge others to do the same. Arrangements are being made, as last year, to seat 200.

We are, Sirs, yours faithfully,
C. Gordon Watson,
Francis E. Fremantle, } Hon. Secs.
39, Moore-street, Lennox-gardens, S.W., April 8th, 1902.

AN APPEAL TO MEDICAL FREEMASONS.

To the Editors of The Lancet.

Sirs,—May I through the medium of your columns appeal to members of the medical profession who are Freemasons for their assistance in the case of my husband, Arthur Somers Ivens, a candidate for the approaching election to the Royal Masonic Benevolent Institution? My husband practised as a surgeon at Thorpe-le-Soken, Essex, for 21 years, but is now, through loss of eyesight and memory consecutive on a severe attack of influenza, an invalid for life and quite unable to follow his profession. He and I are left entirely on friends for support. My husband was initiated in the Arnold Lodge, No. 1799, Walton-on-Naze, on March 4th, 1880, and subscribed until March, 1900. Votes will be thankfully received by

Yours faithfully,

Bildeston, Suffolk. Clara Somers Ivens.

⁂ We understand that this is the only medical case at the approaching election.—Ed. L.

NOTES FROM INDIA.

(From our Special Correspondent.)

The Development of the Plague Epidemic.—The Continued Famine.—The Health Officer of Bombay.—Administrative Changes.

The figures for this week possess several points of interest. First, there is the increased total of plague mortality throughout India from 23,715 to 25,655, chiefly occasioned by the intensity of the disease in the Punjab where 15,090 deaths were recorded, as against 12,544 for the previous seven days. Then the fresh outbreak at such important centres as Delhi and Lahore has to be recorded. Thirdly, the abortive development of the recrudescence in Calcutta and Bengal is to be noticed. In 1901 the plague mortality in Bengal from the first week in February to the second week in March rose from 2200 to 7569, while this year the rise has been from 882 to 1234. Much the same proportionate figures apply to Calcutta. It is evident, therefore, that some epidemic influence is at work inhibiting the development of the outbreak in this particular province. The improved position can hardly be ascribed to the sanitary measures adopted. In other parts of India there is little change. The Madras Presidency returns 361 deaths as against 289, Bombay Presidency 4779 as against 4806, Bombay city 856 as against 888, and Calcutta 501 as against 462. In Karachi the deaths have risen to 82. On the other hand, the outbreak in Poona seems to have run its course. The Bengal Presidency returns 1289 deaths, the North-West Provinces and Oudh—now called the United Provinces—2335, the Mysore State 304, and the Hyderabad State 113. Plague hospitals would seem to be almost things of the past. Very few cases go to the hospitals in Calcutta and on March 11th there were only 181 cases in all the hospitals in Bombay. It may be said that patients are now permitted to die in their own homes. Inoculation is being pushed in some places but is totally neglected in others. For the week ending March 14th 44,179 doses of vaccine were sent out from the laboratory in Bombay.

The famine continues to increase rather than to diminish. On March 10th there were 400,000 persons under relief, chiefly in the Bombay districts, Rajputana, and Central India.

I am glad to be able to record that the services of Dr. J. A. Turner, health officer of Bombay, have met with due appreciation and that his salary has been raised to Rs. 1600 per mensem. In due course it is to be hoped that he will receive the full amount of Rs. 2000 permitted by law.

The following changes will be made in the distribution of military medical administration in India from April 1st. 1. A lieutenant-colonel of the Indian Medical Service will be appointed as principal medical officer of the Derajat district. 2. The appointment of principal medical officer of the Mandalay district, now held by a colonel in the Royal Army Medical Corps, will be abolished. The administrative medical charge embracing Rangoon and the Southern Shan States will be extended to the whole of Burma and the chief appointment will be held alternately by an officer of the Royal Army Medical Corps and one of the Indian Medical

---

[2] The Lancet, Dec. 14th, 1901, p. 1658.

Service, with headquarters at Rangoon. 3. The appointment of principal medical officer of the Peshawar district will be reserved for a lieutenant-colonel of the Royal Army Medical Corps.

March 22nd

BIRMINGHAM

(FROM OUR OWN CORRESPONDENT)

The Ear and Throat Hospital.

THE annual meeting of the friends of, and subscribers to this institution was held on March 18th, when the fifty-seventh annual report was read. It was stated that the expenditure had increased by £214 odd as compared with the previous year The number of new out-patients was 4315 the total number being 7002. 331 in patients had been admitted during the year It was stated that the King had consented to become patron of the hospital Increased accommodation both for patients and for nurses was stated to be imperatively demanded if the present good work is to continue.

Notification of Infectious Diseases

A notice has been issued by the Health Committee of the City Council stating that in future chicken-pox is to be notified under the Infectious Diseases Act. This will include a large number of cases, as at present chicken pox is prevalent in the city Fortunately, no additional cases of small-pox have been notified and as at times it is difficult to differentiate these two diseases in their early stages the precaution of the Health Committee must be looked upon as a wise and well-intentioned regulation.

The Housing Question

The ever present discussions upon this momentous subject still wage with ardour in our midst A site has been secured for the development of a Rowton House and plans have been drawn up which promise to bring to a satisfactory issue the development of this scheme. Meanwhile it is asserted that this project will only touch the fringe of the question and that the great residuum is still unprovided for by town council or private enterprise. The respective parties interested, more especially minor landlords and philanthropists, present very different views on the matter

April 8th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT)

Health of the City

AS recorded in THE LANCET of March 29th, p 924 the jubilee of the Manchester and Salford Sanitary Association is to be held in about a fortnight. The last annual report shows that with comparatively small means the association continues to do valuable work which could scarcely be undertaken by the corporation and certainly not by unorganised private effort. Without being antagonistic to the corporation—and indeed, working amicably with it for the same ends—it can bring influence to bear which not infrequently aids the city council in coming to a wise decision on questions of sanitation. Last year for example, plans were drawn up for building working-class houses by the corporation but in several respects they were faulty and the Sanitary Association and an organisation called the Citizens' Committee succeeded in getting improved plans adopted. The questions of how to bring the advantages of public laundries within reach of the poor and of the formation of a local society for the prevention of consumption are engaging the attention of the association. It continues its efforts to protect the public from the dangers arising from the fumes from chemical works and from the discharge of explosive and poisonous waste products into the sewers. Deputations have been sent to the school boards of Manchester and Salford to advocate the teaching of hygiene and work has been done in various other directions. In one thing there has been failure—namely, in convincing the corporation of the need of cottage baths in the crowded parts of the city The Baths Committee of the corporation more than 12 months since said that they had the matter under consideration, and it appears to be under consideration still. As the Lord Mayor presided at the annual meeting and promised to talk over the question with the chairman of the Baths Committee perhaps there may be some hope of this boon to poor women being granted The association also endeavours to spread the knowledge of sanitary matters by lectures and by the publication of tracts and leaflets It may perhaps have been noted that the Congress of the Sanitary Institute is to be held in Manchester in September next, so that the question of the public health will be brought with unusual prominence this year before the people of Manchester

Meeting-place for Scientific Societies

Manchester has long suffered from the want of a central meeting place and library for its various scientific societies The Literary and Philosophical Society, the oldest and as regards its history the most distinguished of them, is fortunate in having its own domicile but it cannot accommodate all the others A meeting was held in the Town Hall on April 3rd to consider the question. In the unavoidable absence of the Lord Mayor Mr Alfred Darbyshire presided. Members of the following societies were present the Geographical Society, the Association of Engineers, the Section of the Institution of Electrical Engineers, the Chemical Club the Medical Society, the Pathological Society, the Clinical Society, the Microscopical Society, the Society of Architects, the Amateur Photographic Society, the Geological Society, the Field Club and the Society of Chemical Industry At present these 13 societies, as one of the speakers remarked, "have to meet in some hired room, usually in an hotel, and speaking from experience this was not at all satisfactory and did not tend to promote the dignity of the meetings." The various medical societies have long felt this state of things as a great inconvenience and attempts have been made more than once to obtain more suitable quarters but the cost has been found to be prohibitive. The Medical Society at present is accommodated at Owens College, in the rooms of which its library of 26,000 volumes is lodged, but the requirements of the college as to space are continually growing and this arrangement cannot be looked upon as permanent. Dr T Harris (Medical Society) moved that a committee should be formed, with power to add to its number, to consider the question of a central meeting place and to prepare a scheme or schemes. This was carried and it may be hoped that by coöperation the societies will succeed in accomplishing what they cannot do singly

The Medical Inspection of Schools

Dr Arnold W W Lea has drawn attention in the local papers to the great need there is in Manchester and Salford for more thorough medical inspection of public elementary schools and of the scholars. The Salford School Board appointed a medical officer some years ago and the Manchester School Board has recently decided to do so Attendance at school being compulsory it is only just that the school authorities should see that the health of the children does not suffer and that they should, as far as possible, be protected 'from the infectious and loathsome diseases so prevalent in schools" The London School Board by means of elaborate instructions and pamphlets hopes that the teachers may become sufficiently skilled, and that they will be on the alert, to detect disease among the children " But, as Dr Lea says, this "can really form no part of a teacher's work and is of comparatively little value." Much the same may be said of the appointment of nurses as adopted in some schools and approved apparently by the Board of Education "to detect and treat diseases, though it admits that for this purpose they would require special skill and instruction ' This would seem to be adding another class of "inferior," but no doubt "certificated " practitioners who by degrees seem to be ousting the unhappy general practitioner In Manchester there are about "40,000 children daily attending elementary schools' and it is impossible for one man to supervise the hygienic conditions and the health of the children, even if the whole of his time were devoted to the work, which, it is stated, is not expected Dr Lea says that in America the medical supervision is very completely carried out, though most European countries seem to have done more than we have in this direction. In Boston, U S.A., a medical officer attends each school every morning between 9 and 10 A.M He sees all children observed by the teachers to be ailing or whose parents wish for an examination. If the child is not fit to be at school a card telling the nature of the complaint and advising as to the steps to be taken is sent to the parents. The inspector does not undertake the intermit, which occurred several times during the first 48 hours. This patient had 1865 minims of the liquor in 64 days without the slightest symptom of poisoning but with marked benefit to her heart.

3. I have recently anæsthetised a man, aged 30 years, suffering from tuberculous peritonitis for which cœliotomy was performed, the lungs being also affected. Chloroform was given in preference to ether because of the lung affection. The anæsthesia lasted one hour, at the end of which his pulse became very feeble, almost running, the rate being about 190. I injected 20 minims of liquor strychninæ into the substance of the left pectoralis major; in about seven minutes the pulse improved considerably in strength with its rate reduced to 120 No symptoms of poisoning resulted.

4. Mr. B. G. A. Moynihan[2] has recorded a case of double primary amputation, on the right side at the hip-joint, on the left side in the middle of the thigh, in which 45 minims of liquor strychninæ were given hypodermically in three-quarters of an hour, producing good stimulation but no symptom of poisoning.

From the above and other similar cases it is evident that strychnine may be administered to combat cardiac failure in doses much larger and more frequent than is usually considered safe. Patients in a state of collapse stand these larger doses well, their administration causing marked improvement in the pulse, usually without any twitching. Even where some twitching occurs it is of comparatively little importance. It is of little use to inject strychnine under the skin of an extremity in a pulseless patient, the circulation of the part in such a case being almost non-existent. It is quite possible by making frequently repeated subcutaneous injections of strychnine into the extremity of a pulseless patient to cause convulsions, because, if the patient's circulation improves—as, for instance, after intravenous injection of saline solution—the strychnine which has accumulated in the subcutaneous tissues is rapidly absorbed owing to the improved circulation, the patient getting within a short space of time the whole amount of the hypodermic injections. The ideal method of introducing strychnine into the general circulation is to give it with the saline solution when intravenous infusion is being performed. I have had no experience of injecting undiluted liquor strychninæ into a vein. A useful place for injection is the pectoralis major, the drug being injected into the substance of the muscle. This site has the additional advantage that if artificial respiration is being performed the drug is massaged into the circulation. The Madras Presidency returns 361 deaths as against 289, Bombay Presidency 4779 as against 4806, Bombay city 856 as against 888, and Calcutta 501 as against 462. In Karachi the deaths have risen to 82. On the other hand, the outbreak in Poona seems to have run its course. The Bengal Presidency returns 1289 deaths, the North-West Provinces and Oudh—now called the United Provinces—2335, the Mysore State 304, and the Hyderabad State 113. Plague hospitals would seem to be almost things of the past. Very few cases go to the hospitals in Calcutta and on March 11th there were only 181 cases in all the hospitals in Bombay. It may be said that patients are now permitted to die in their own homes. Inoculation is being pushed in some places but is totally neglected in others. For the week ending March 14th 44,179 doses of vaccine were sent out from the laboratory in Bombay.

The famine continues to increase rather than to diminish. On March 10th there were 400,000 persons under relief, chiefly in the Bombay districts, Rajputana, and Central India.

I am glad to be able to record that the services of Dr. J. A. Turner, health officer of Bombay, have met with due appreciation and that his salary has been raised to Rs. 1600 per mensem. In due course it is to be hoped that he will receive the full amount of Rs. 2000 permitted by law.

The following changes will be made in the distribution of military medical administration in India from April 1st. 1. A lieutenant-colonel of the Indian Medical Service will be appointed as principal medical officer of the Derajat district. 2. The appointment of principal medical officer of the Mandalay district, now held by a colonel in the Royal Army Medical Corps, will be abolished. The administrative medical charge embracing Rangoon and the Southern Shan States will be extended to the whole of Burma and the chief appointment will be held alternately by an officer of the Royal Army Medical Corps and one of the Indian Medical

---

Service, with headquarters at Rangoon. 3. The appointment of principal medical officer of the Peshawar district will be reserved for a lieutenant-colonel of the Royal Army Medical Corps.

March 22nd

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT)

The Ear and Throat Hospital.

THE annual meeting of the friends of, and subscribers to, this institution was held on March 18th, when the fifty-seventh annual report was read. It was stated that the expenditure had increased by £214 odd as compared with the previous year The number of new out-patients was 4315, the total number being 7002 331 in patients had been admitted during the year It was stated that the King had consented to become patron of the hospital. Increased accommodation both for patients and for nurses was stated to be imperatively demanded if the present good work is to continue.

Notification of Infectious Diseases

A notice has been issued by the Health Committee of the City Council stating that in future chicken-pox is to be notified under the Infectious Diseases Act. This will include a large number of cases, as at present chicken pox is prevalent in the city Fortunately, no additional cases of small pox have been notified and as at times it is difficult to differentiate these two diseases in their early stages the precaution of the Health Committee must be looked upon as a wise and well-intentioned regulation.

The Housing Question

The ever present discussions upon this momentous subject still wage with ardour in our midst A site has been secured for the development of a Rowton House and plans have been drawn up which promise to bring to a satisfactory issue the development of this scheme. Meanwhile it is asserted that this project will only touch the fringe of the question and that the great residuum is still unprovided for by town council or private enterprise. The respective parties interested, more especially minor landlords and philanthropists, present very different views on the matter

April 8th

MANCHESTER

(FROM OUR OWN CORRESPONDENT)

Health of the City

AS recorded in THE LANCET of March 29th, p 924, the jubilee of the Manchester and Salford Sanitary Association is to be held in about a fortnight. The last annual report shows that with comparatively small means the association continues to do valuable work which could scarcely be undertaken by the corporation and certainly not by unorganised private effort. Without being antagonistic to the corporation—and, indeed, working amicably with it for the same ends—it can bring influence to bear which not infrequently aids the city council in coming to a wise decision on questions of sanitation. Last year, for example, plans were drawn up for building working-class houses by the corporation but in several respects they were faulty and the Sanitary Association and an organisation called the Citizens' Committee succeeded in getting improved plans adopted. The questions of how to bring the advantages of public laundries within reach of the poor and of the formation of a local society for the prevention of consumption are engaging the attention of the association It continues its efforts to protect the public from the dangers arising from the fumes from chemical works and from the discharge of explosive and poisonous waste products into the sewers. Deputations have been sent to the school boards of Manchester and Salford to advocate the teaching of hygiene and work has been done in various other directions In one thing there has been failure—namely, in convincing the corporation of the need of cottage baths in the crowded parts of the city The Baths Committee of the corporation more than 12 months since said that they had the matter under consideration, and it appears to be under consideration still. As the Lord Mayor presided at the annual meeting and promised to talk over the question with the chairman of the Baths Committee perhaps there may be some hope of this boon to poor women being granted. The association also endeavours to spread the knowledge of sanitary matters by lectures and by the publication of tracts and leaflets It may perhaps have been noted that the Congress of the Sanitary Institute is to be held in Manchester in September next, so that the question of the public health will be brought with unusual prominence this year before the people of Manchester

Meeting place for Scientific Societies.

Manchester has long suffered from the want of a central meeting place and library for its various scientific societies The Literary and Philosophical Society, the oldest and as regards its history the most distinguished of them, is fortunate in having its own domicile but it cannot accommodate all the others A meeting was held in the Town Hall on April 3rd to consider the question. In the unavoidable absence of the Lord Mayor Mr Alfred Darbyshire presided. Members of the following societies were present · the Geographical Society, the Association of Engineers, the Section of the Institution of Electrical Engineers, the Chemical Club, the Medical Society, the Pathological Society, the Clinical Society, the Microscopical Society, the Society of Architects, the Amateur Photographic Society, the Geological Society, the Field Club, and the Society of Chemical Industry At present these 13 societies, as one of the speakers remarked, "have to meet in some hired room, usually in an hotel, and speaking from experience this was not at all satisfactory and did not tend to promote the dignity of the meetings" The various medical societies have long felt this state of things as a great inconvenience and attempts have been made more than once to obtain more suitable quarters but the cost has been found to be prohibitive. The Medical Society at present is accommodated at Owens College, in the rooms of which its library of 26,000 volumes is lodged, but the requirements of the college as to space are continually growing and this arrangement cannot be looked upon as permanent. Dr T Harris (Medical Society) moved that a committee should be formed, with power to add to its number, to consider the question of a central meeting place and to prepare a scheme or schemes. This was carried and it may be hoped that by coöperation the societies will succeed in accomplishing what they cannot do singly

The Medical Inspection of Schools

Dr Arnold W W Lea has drawn attention in the local papers to the great need there is in Manchester and Salford for more thorough medical inspection of public elementary schools and of the scholars. The Salford School Board appointed a medical officer some years ago and the Manchester School Board has recently decided to do so. Attendance at school being compulsory it is only just that the school authorities should see that the health of the children does not suffer and that they should, as far as possible, be protected "from the infectious and loathsome diseases so prevalent in schools" The London School Board by means of elaborate instructions and pamphlets hopes that the teachers may become sufficiently skilled and that they will be on the alert, to detect disease among the children" But, as Dr Lea says, this "can really form no part of a teacher's work and is of comparatively little value." Much the same may be said of the appointment of nurses as adopted in some schools and approved apparently by the Board of Education "to detect and treat diseases, though it admits that for this purpose they would require special skill and instruction." This would seem to be adding another class of "inferior," but no doubt "certificated," practitioners who by degrees seem to be ousting the unhappy general practitioner In Manchester there are about "40,000 children daily attending elementary schools" and it is impossible for one man to supervise the hygienic conditions and the health of the children, even if the whole of his time were devoted to the work, which, it is stated, is not expected Dr Lea says that in America the medical supervision is very completely carried out, though most European countries seem to have done more than we have in this direction In Boston, U S A., a medical officer attends each school every morning between 9 and 10 A.M He sees all children observed by the teachers to be ailing or whose parents wish for an examination. If the child is not fit to be at school a card telling the nature of the complaint and advising as to the steps to be taken is sent to the parents. The inspector does not undertake the treatment which must be carried out through the parents. The child is again inspected before being allowed to return to school. The same system is carried out in many other cities. "The expense of such a system would be by no means great and would be more than balanced by (1) a diminution in the number of cases of infectious disease; (2) increased school attendance; and (3) improved health of the children." The Manchester School Board estimates that through measles alone the elementary schools of Manchester lose £2000 per annum. In view of the acknowledged rapid "physical deterioration of the youth of our great cities" it is of high importance to neglect no means of checking what is already a national peril.

Poisoning by Mond Gas.

An inquest was held at Leeds on April 3rd on the body of a man who was found unconscious, face downwards, on a pipe conveying Mond gas. Artificial respiration was tried to no purpose. It was thought that in repairing a leak in the pipe he "had slipped and, knocking his head against one of the pipes, had become unconscious" and so had inhaled the gas. Mr. F. W. Halliday, the surgeon who was called in, said that he was satisfied that death was due to carbon monoxide poisoning. Shortly after the accident it was found that one sample contained 10·2 and another 12·6 per cent. of the monoxide. One point tending to the prevention of accidents is that the smell is said to be "awful" and can be detected 30 yards away. This is due to the tarry matter in the coal. The managing director of the works said that the gas was not dangerous to the public or to the workmen "with ordinary care" and, the coroner agreeing with him, the jury returned a verdict of "Accidental death." It is obvious, however, that leakage of the gas should be carefully guarded against, first, because of its large percentage of carbon monoxide, and secondly, because it would be a serious nuisance.

Barrow Hospital Inquiry.

His Honour Judge Parry held an inquiry on April 5th at Barrow concerning complaints of delay in the treatment of patients at the hospital. As his report has not yet been given it is undesirable to comment on the case, but it seems to turn very much on whether the one house surgeon of the hospital can be always on duty.

April 8th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Memorial to a Northumberland Volunteer.

ON Saturday, April 5th, in North Gosforth Cemetery, Sir George Hare Philipson unveiled a monument erected in memory of the late Dr. W. L. Walker, of Seaton Burn, Northumberland, who was killed in action at Modderfontein, South Africa, on Jan. 31st, 1901, whilst endeavouring to save a comrade. The monument, which is of grey polished granite and about 10 feet in height, is surmounted by a red granite Latin cross. On the base is the following inscription:

> In memory of William Longstaff W. Walker, M.D., B.S. (Durham), of Seaton Burn, civil surgeon, 2nd South Wales Borderers. Killed in action at Modderfontein, Transvaal, South Africa, January 31st, 1901. Aged 26 years. For his country. Erected by friends of Seaton Burn and Dinnington Collieries and District.

Sir George Hare Philipson spoke of the brilliant career of the deceased as a student at Durham College of Medicine, Newcastle, as well as of his late valuable work in the Royal Infirmary and the Dispensary, Newcastle. Dr. Walker, he said, won the esteem of all with whom he was there brought into contact. Animated by a desire to serve his Queen and country, when the war in South Africa broke out he volunteered, along with his brother Allan, for active service and in the year 1900 he was sent out as a civil surgeon with the 2nd South Wales Borderers. He proved an active and gallant volunteer and took a full share in the operations at Bloemfontein, Krugersdorp, Magersfontein, and Modderfontein. On Jan. 31st, 1901, whilst endeavouring to save an orderly, he received a wound which speedily proved fatal. That heroic act was but a sample of the self-sacrifice which constituted a prominent feature of his noble character. His bravery was conspicuous everywhere and even the Boer commanders bore testimony to his gallantry in the field. Though his body had been laid to rest on a kopje with the remains of the orderly whose life he had endeavoured to save they believed his soul was now with his Maker. The beautiful memorial bore silent but eloquent testimony to the regard which they all felt for his memory.

Death of James M. Fraser, M.B., C.M. Edin., Coxhoe, Co. Durham.

Dr. J. M. Fraser died at the Davy Lamp Surgery on April 3rd, where he acted as assistant to Dr. W. A. Hepburn of Coxhoe. It appears that at about 2 P.M. on that day he told his housekeeper that he was going to lie down, as he was tired, and he asked her to awaken him at about 6 o'clock. She went to awaken him at that time but could not do so. She then sent immediately for Dr. Hepburn, who when he arrived did everything possible for him but without avail. An inquest was held two days later and the jury returned the following verdict: "Death from the effects of an overdose of morphia, but whether taken intentionally or otherwise we are unable to decide."

Durham University Convocation.

A Convocation will be held in the library of the College of Medicine, Newcastle-upon-Tyne, on Saturday, April 26th, at which it is proposed to confer the honorary degree of D.C.L. on Sir William Selby Church, Bart., President of the Royal College of Physicians of London, and Professor Thomas Annandale, Regius Professor of Clinical Surgery in Edinburgh University.

Small-pox.

Cases of small-pox have now been occurring in this district for the last two months but with two or three exceptions the infected area has been confined to North and South Shields. The number of cases in North Shields since the outbreak is 42, while there are at present 13 cases in the hospital at South Shields. A meeting of the health committee of Durham County Council was held in the Shire Hall, Durham, on April 7th, to consider the question of isolation accommodation in the county in view of the possible increase of the disease during the summer months.

Newcastle-on-Tyne, April 8th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Typhoid Fever in Brecknockshire.

DURING the past 30 years the population of the rural district of Crick[illegible] has fallen from 8514 to 7116 and for a great [illegible] of the same period typhoid fever has been ende[illegible] the district. In the year 1883 the then medical officer of health stated that with regard to one locality "newcomers usually have the disease during the first year of their residence there." Last year among a group of some 200 houses 40 cases were reported and as the infection was attributed by the medical officer of health (Mr. P. E. Hill) to the pollution of springs supplying water to the houses affected an inspection of the locality was made in September last on behalf of the Local Government Board and the report of the inspectors, Dr. R. J. Reece and Mr. Sandford Fawcett, A.M.I.C.E., has now been published. This report discloses a most unsatisfactory condition in the rural district, where springs used as domestic water-supplies are not only contaminated with cesspools and slop drains but also from the leaking pipes of a length of sewer which carries sewage from the adjoining urban district of Brynmawr. After detailing certain recommendations the writers of the report go on to say: "What is brought home to us in our inquiry is the fact that if the rural district council had carried out the recommendations first made to them in 1872 by Dr. Gwynne Harries (an inspector of the Local Government Board) many deaths and much suffering would in all probability have been prevented."

Small-pox.

During the week ending April 5th there were seven fresh cases of small-pox in Swansea, all the patients being men, and it is probable that they were infected from the same source. There are three cases of small-pox in the county of Hereford. One patient is a man who had tramped from London; the other two are children who have presumably been infected from some tramp or other person passing through the district.

The Examination of Children's Teeth

A committee of the Cardiff Board of Guardians recently had before it a communication from the honorary secretary of the South Wales Branch of the British Dental Association in which the importance of a regular examination of the teeth of the children under the committee s charge was urged. According to the report in the local newspapers the communication was received with "bursts of ironical laughter' If this reception is a measure of the manner in which the pauper children of Cardiff are cared for in other respects it is exceedingly probable that a large number will become, and will remain, pauper men and women The members of the committee appear to forget that as regards the children under their care they are *in loco parentis* and at the present time a parent who has any regard for the comfort and future welfare of his children recognises that a regular visit to the dentist is as essential as the provision of suitable food or of seasonable clothing

The Manufacture of Ice cream

The health committee of the Bristol Corporation has been considering the expediency of obtaining local powers for the more effective control of ice-cream manufactories within the city, and has recommended that in the next Bill promoted by the corporation certain powers should be inserted with this end in view The provisions suggested by the committee are that every maker of, or dealer in, ice cream shall give immediate notice to the medical officer of health of any outbreak of infectious disease amongst the persons employed in the business and that no persons shall be employed in the manufacture or sale of ice-cream while he is suffering from diarrhœa, typhoid fever, scarlet fever, diphtheria, or other infectious disease or from any infectious skin disease Further suggestions are that ice-cream shall not be made in a room in which there is any inlet or opening to a drain in a room used as a living or sleeping room or which communicates directly with a privy or ashpit, or where the articles used in the manufacture are likely to be contaminated The frequent washing or scalding of utensils used in the process of manufacture, the lime washing of walls and ceilings twice yearly, and the washing of floors once a week are provided for, and, finally, the use of ice from ponds, canals, or streams in the neighbourhood of the city is prohibited.

IRELAND.

(From our own Correspondents.)

Curious Defence for Poor Milk.

At the Belfast Police-court on April 7th two men were summoned for selling milk which was 13 3 per cent. deficient in normal fats. The defence was that the milk was sold as it came from the cow at the end of February in cold snowy weather and that there were times, especially in the winter, when through cold or change from one temperature to another there might be a falling off in fats In such circumstances the animal itself had to fall back to a slight extent upon the fats which were in its composition for the purpose of keeping up the heat and that might be a reason for the falling-off in the fat and for the alteration in the character of the milk It was stated that there had been a decision in England in which the magistrates held that though the milk was pure milk it was of bad quality and that they had fined the defendant but that on appeal to the King's Bench Division it was held that the conviction could not stand. In order that the decision might be looked up the case was adjourned for two weeks.

The Royal Commission on University Education in Ireland

This Commission met in Belfast last week and held two sittings (morning and afternoon) on April 2nd, 3rd, and 4th and a morning session on the 5th—that is, altogether the members of the Royal Commission have devoted three and a half days to Belfast. During this time they examined or, to be more accurate they heard (for of any real attempt at examination there was almost none) written statements from 32 different witnesses dined one evening at Queen's College with the professors, and attended an afternoon reception on the 4th at the house of the President of Queen s College. Among members of the medical profession the following gave evidence Professor J Symington, Professor J W Byers, Professor J A. Lindsay, Professor T Sinclair, Dr A. Dempsey, Dr W Calwell (honorary secretary to the medical and surgical staff of the Royal Victoria Hospital), and Dr R. W Leslie (secretary of the Royal University Graduates Association) The chairman (the Right Hon Lord Robertson) was most courteous and showed himself determined to give everyone a full hearing, but, writing quite candidly, I may say that public opinion in Belfast and the north of Ireland has not been reassured by the circumstance, so little concealed, that little or no attempt should have been made, as was done in other places, to question the witnesses. The Commissioners, rightly or wrongly, have given the impression to the public, conveyed probably through the witnesses, that their desire was to get through work as rapidly and as civilly as possible, that they had already heard enough evidence and that their minds were made up The result is that public opinion in Belfast, which has always been hostile to the Commission from the fact that there was not a single member appointed on it who was regarded as holding the views of the majority of the Belfast people, has become more antagonistic, and the statement made in one of the local papers that the evidence of Mr F Hugh O Donnell and also that of Professor Hartley and Professor O Reilly (of the Dublin College of Science) has been refused has not tended to improve matters. There may be clear and definite reasons for the exclusion of these witnesses, but after their public declaration on the matter the Commission should give some explanation on the subject. The evidence will not be printed for some time, but the features of it specially canvassed are the statement of the President of Queen's College that he wished that institution to be a university in everything but in name, the extraordinary revelations in reference to the working of the Royal University in its relation to the Belfast medical school, the strongly expressed views advocating a complete reform in the government of the Queen s College, Belfast, the divergence of views as to the settlement of the question of university education in Ireland, the strong case made out for a women's college in Belfast, the claims of the Belfast and Ulster Roman Catholics to be consulted in the settlement, and the views of the graduates The Commissioners met at Magee College Londonderry, on April 7th, and heard two witnesses, and on April 8th, in the afternoon, they met at Galway They will now go to Cork and it is said that later they will hear, at their concluding session in Dublin, some more witnesses after which it is believed they will try to come to some decision on this vexed question.

The late Michael M'Donnell, M R C S Eng , J P , of Belfast

I regret to announce the death of Mr M. M'Donnell, a most highly respected and greatly beloved medical man at his residence in Belfast on April 3rd For a long time Mr M'Donnell practised in Randalstown, where he was certifying factory surgeon and medical attendant to the Royal Irish Constabulary He obtained the Membership of the Royal College of Surgeons of England in 1847 and was one of the senior medical practitioners of the North of Ireland A short time ago he gave up the active duties of his profession and came to reside in Belfast, where his son is in practice

Training of Nurses in Lurgan Workhouse

At a meeting of the Lurgan Board of Guardians on April 3rd it was decided to adopt the recommendations of the committee of the infirmary who had advised that the salary of Dr J S Darling the visiting medical officer of the workhouse should be increased by £25 per annum, that the nursing staff of the establishment should consist of four charge nurses and eight probationers, and that probationers should be employed for two instead of three years as proposed and that the only salary paid to probationers should be £6 for the second year The result of this decision is that Lurgan will be accepted as a training school for nurses

PARIS

(From our own Correspondent)

The Insanity of Dr Boileux

Some six years ago Dr Boileux and Dr de la Jarrige were convicted of procuring criminal abortion and were sentenced to five years imprisonment. They were released on completing half their sentence At the time of the trial many persons believed that a gross miscarriage of justice had taken place. The facts were as follows. Dr. Boileux curetted the uterus of a woman who had been sent to him by his colleague, Dr. de la Jarrige, with a diagnosis of metritis. In the course of the operation Dr. Boileux found that the woman was pregnant. However, he went on with the curetting and finally perforated the uterus. This set up peritonitis from which the woman died despite a laparotomy being performed. The circumstances attending the operation were somewhat mysterious. Dr. Bolieux did not operate on the patient in his private hospital but in his own private house, making her go to bed in his own room. Some correspondence between the lover of the woman and Dr. de la Jarrige, which was seized, showed that the latter at least knew perfectly well that his patient was pregnant. The lover committed suicide at the beginning of the trial. It was never clearly established that Dr. Boileux knew of the pregnancy and it is quite possible that he was led into error by trusting to the diagnosis of Dr. de la Jarrige. Once out of prison the unhappy Dr. Boileux led a miserable existence. After trying to get a living as assistant to a surgical instrument-maker and then as secretary to a medical man he tried to recommence practice, incited thereto by some of his friends who believed in his innocence. But his name was enough and he got no patients. Some few days ago he became furiously maniacal and going into a restaurant commenced to smash everything that he could lay his hands on. The unhappy man is now in a lunatic asylum.

Raw Vegetables and Sewage.

M. Baudin, Minister of Public Works, is much exercised at the effects which fruits and vegetables which have been watered with sewage may have on the public health of Paris when they are eaten raw. He has therefore written a letter to the President of the Council proposing that measures should be taken to obviate this risk and pointing out that there is every reason to fear that fruits and vegetables contaminated by sewage efflux which has been insufficiently purified arrive at the markets infected with microbes and organic débris. The water used for irrigation distributes the pathogenic organisms and boiling makes these harmless. Cooked vegetables and fruits which are peeled before being eaten are therefore free from risk, but it is very far from being the same with vegetables and fruits which are eaten raw, such as salads and strawberries. M. Baudin only sees one way of obviating this risk and that is to have a clause in the contracts between the Paris authorities and the users of sewage for cultivation forbidding the latter to use sewage for fruits and vegetables intended to be eaten raw. In accordance with this proposal the Consultation Committee of Public Health nominated a sub-committee which has decided that such a clause shall be inserted in forthcoming contracts.

The Diagnosis of the Nature of Blood-stains.

At the meeting of the Academy of Medicine held on March 25th M. Linossier and M. Lemoine gave an interesting account of the present methods of diagnosing the origin of a blood-stain. Until quite lately the expert could only say with certainty that the stain gave corpuscles which were nucleated and elliptical as in birds or discoidal as in mammals (except the camel) and occasionally in very favourable specimens he could differentiate human globules from the very small ones of the musk deer, but no difference could be certainly ascertained between the globules of man and those of the dog or of the rabbit. Experts in forensic medicine have therefore taken great interest in the method newly proposed by Uhlenluth, founded on the serum precipitation process of Tschistovitch and Bordet. The method is as follows. A rabbit is given gradually increasing doses of human serum which is toxic for the rabbit. After a certain time the rabbit becomes immune and then the serum of its own blood when brought into contact with human blood gives under the microscope a characteristic precipitate. If then a number of prepared rabbits were kept in readiness the expert would be able, it was claimed, to recognise whether a blood-stain is human or not. However, other observers contested this statement and said that the blood of other mammals besides man gave a similar precipitate. Thus confusion arose which made the method of little value. In their communication of March 25th M. Linossier and M. Lemoine showed that the method could be rendered accurate by taking the precaution to use serum diluted with water. Rabbit's serum in a strength of 1 in 1000 always gave a precipitate with human blood but not with that of another animal.

The Overcrowding of the Paris Hospitals.

During the winter and the early spring the Paris hospitals are much overcrowded and in order to overcome this difficulty the Director of the Assistance Publique caused notices to be posted in all the out-patient rooms to the effect that the Paris hospitals existed for the use of the inhabitants of Paris only. However, of course, if a patient shivering with fever presented himself for admission the physician in charge had to take him in. The director of the Assistance Publique has now come to a decision which it is hoped will have the result of relieving the overcrowding. All patients who are so far advanced in convalescence as not to need constant care will be transferred to their own homes. There they will still be provided with medical attendance and medicines free of charge and they will besides be allowed a sum of one franc per diem for the space of one month, which term may be extended to three months on a certificate signed by the medical attendant. This new rule will not, of course, be strictly enforced except in the case of those who have a fairly good home and some relation capable of looking after them.

April 8th.

SWITZERLAND.

(From our own Correspondent.)

A New Water-supply for Zürich.

At present the town of Zürich has a double water-supply. Water for household purposes derived from the lake, properly filtered in double sand filters, flows into almost every house in the town and amply provides for purposes of street-cleaning, &c. It is for the most part bacteriologically so pure that a majority of the population use it for drinking purposes, though about 200 public fountains supply pure and fresh water derived from springs (*Quellen*) situated in the forests above the town. During the 15 years from 1885 to 1900 the population increased greatly and it now amounts to 150,000. A daily supply of 45,000 cubic metres (9,900,000 gallons) is therefore required instead of 25,000 cubic metres (5,500,000 gallons) as before. The municipality has been fortunate enough to secure by purchase a number of springs situated in the Sihl and Lorze valleys, some 15 miles from the town at an altitude of 552 metres. This water, which is bacteriologically of the purest kind, is carried round the town through a circular system of pipes from which branches will eventually supply 200 new fountains to be erected in suitable situations throughout the city. The total quantity of water available amounts to 23,000 cubic metres (5,060,000 gallons) per diem, thus securing an ample supply of the best and purest drinking-water for Zürich for a long course of years. Running water was deemed essential by the hygienists consulted (Professor Oscar Wyss and Professor Roth) as ensuring purity. The town will spend a sum of 3,200,000 francs (£128,000) to complete the work. The aqueduct is already made, 7500 cubic metres (1,650,000 gallons) of water are already available, and the rest of the fountains will be built at intervals in the course of the next three years.

Medical Students at Swiss Universities.

The total number of medical students inscribed for the winter term of 1901–1902 amounted to 1493. The special feature at present is the progressive increase of foreign female students, which is so rapid that the men will in two or three years' time be in the minority. There were 665 women and 828 men. Only 600 students (580 male and 20 female) were Swiss and the rest (893) were foreigners of whom 645 women. The number of students at the different universities was as follows: Basle, 147; Lausanne, 202; Zürich, 291; Geneva, 396; and Bern, 457. There were only five female students at Basle; the ladies have a great preference for Bern, where they number 283 and leave the men in a minority of 174.

Zürich, April 4th.

Protection for Football Players. — An American inventor has patented a "head harness for football players." The specification and a drawing will be found in the weekly number of the official *Gazette* of the United States Patent Office issued on March 11th, 1902.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At the Primary Examination the following candidates passed in the subjects indicated :—

PART I.

Biology—S. F. H. Everill, Birmingham, and C. E. Pring, Royal Free Hospital.

Chemistry.—S. F. H. Everill, Birmingham, and J. C. Fletcher, Royal Free Hospital.

Materia Medica and Pharmacy.—M S. Jevons, Royal Free Hospital; T. Lea, Glasgow and Bristol; J. G. Lewis, Cardiff; E. H. Price, Birmingham; and E. Sergeant, Royal Free Hospital.

PART II.

Anatomy—G. H. Almond, Cambridge and Leeds; A. Bernfeld, Royal Free Hospital; E P. J. Dawes, Birmingham; L Doudney, Guy's Hospital; A. G. O. Findlay, University College Hospital; A. G. Gamble, Leeds; H. S. Gettings, Birmingham; G. P. K. Grey, Middlesex Hospital; C. Homer, St. Mary's Hospital and Bristol; L. J. Paterson-Clavier, Guy's Hospital; J. W. Peatt, London Hospital; J. O. Sergeant, Leeds; F. A. K. Stuart, St. Mary's Hospital; R. J. C. Thompson and J. A. R. Wells, St. Thomas's Hospital; and P. B. Whitington, London Hospital.

Physiology.—A. Bernfeld, Royal Free Hospital; L. Doudney, Guy's Hospital; F. C. M. Gabites, Edinburgh; H. S. Gettings, Birmingham; J. O. Johnson, Middlesex Hospital; J. G. Lewis, Cardiff; G. B. Messenger, Westminster Hospital; L J. Paterson-Clavier, Guy's Hospital; J W Peatt, London Hospital; R. J. C. Thompson, and J. A. R. Wells, St Thomas's Hospital; and P. B. Whitington, London Hospital.

UNIVERSITY OF GLASGOW.—The following have passed the first professional examination for the degrees of Bachelor of Medicine (M.B) and Bachelor of Surgery (Ch.B.) in the subjects indicated (B., Botany; Z., Zoology; P., Physics; C., Chemistry).

George Victor Anderson (P., C), James Montgomery Anderson (Z , C.), Andrew Hamilton Arnott (P), George Duncan Morrison Beaton (P.), Donald Price Bremner (Z., P.), William Archibald Campbell (Z., C.), Donald Livingston Carmichael (C.), Charles Game Angus Chislett (B.*, C), Henry Howard Christie (Z., C.), John Sawers Clark (Z., C.), Andrew Donaldson Cowan (B *, P.), Thomas Lawson Craig (Z.*, C.) Arthur Muir Crawford (Z., C.), Robert Donald (Z.), Richard John Driscoll (B), James Dunbar (B.), Allan Dunsmuir (Z.), Eric John Dyke (P.), Ernest Milne Eaton (Z *, C.), William Miller Fairlie (Z., C), Thomas Scott Forrest (P., C.), James Wilfrid Georgeson (Z., P.), William Gilbert (Z., C *), William Gilfillan (C.), Percy Frederick Grant (Z., C.), Arnold Harris Gray (B., Z., P.), Robert Neil Guthrie (Z.*, C.), John Hammond (P.), William Towers Hardie (Z.), Robert M'Cowan Hill (P.*), John Keys (Z., C.), James Dunlop Kidd (Z), George Hugh Logan (B., P.), Angus Macaulay (B.), Alexander M'Call (Z , C), John M'Cartney (P.), Thomas M'Cosh (P., C), David MacDonald (Z., C), James M'Farlane (Z., C.), John Robert M Gilvray (Z , C.), William Anderson M Kellar (Z.), Thomas Cooper Mackenzie (Z.), William Ferguson Mackenzie (Z.*, C.), William Macleod (B , P., C.), John M'Millan (B., Z. P , C.), Alister Argyle Campbell M Neill (Z., C), Charles James Colquhoun Macquarie (Z.*, C.), Andrew Maguire (Z., P.), Robert Marshall B., Z), Robert May (P.), Allan Frederick Miller (C.), John Miller (Z.*, C.), Robert Stewart Miller (Z), William Miller (Z.), Peter Mitchell, M A. (B.*, Z.*), Robert Wright Mitchell (Z.*), William Struthers Moore (B , P.*), Archibald Naismith (B , Z), Patrick Joseph O Hare (B., P.), John Oswald (Z , P), James Hogg Paul (Z , C), Daniel M'Kinlay Reid (Z., P.), John Reid (B., P.), Frederick Gordon Robertson (Z., C.), James Henry Anderson Robertson (Z., P.), Murdoch Mann Rodger (B.) William James Rutherfurd (Z., C.*), John Sharp (Z., C.), Robert Wilfrid Simpson (P.), Robert Alexander Slater (C.), Thomas Baillie Smith (Z , C), James Stevenson (C), John Stevenson (Z * C.), Archibald Stewart (Z., P.), John Torrance Weir Stewart (B., Z.), Thomas Strain (P.), David Laurence Alexander Tate (B., Z), Charles Samson Thomson (Z. C.), Hugh White (Z.), David John Williams (Z.), George Haswell Wilson (Z. C), Samuel Wilson, M.A (Z., C.), William Alexander Wilson (P.), and Thomas Winning, M.A. (B., Z.).

Women.—Jeannie Montgomery Andrew (P.*, C.), Annie Rennie Bird (P., C.), Rose Isobel Hudson (P *, C.), Agnes M'Phun (Z.), Edith Oversby (P., C.), Vera Dagmar Reis (P.*, C.), Margaret Baillie Taylor (C.), and Christina Gibson Thomlinson (B., Z.).

The following have passed the second professional examination for the degrees of Bachelor of Medicine (M.B) and Bachelor of Surgery (Ch.B.) in the subjects indicated (A., Anatomy; P., Physiology; M., Materia Medica and Therapeutics) :—

Scott Campbell Adam (A., P.), Archibald Craig Amy (A., P., M.), Henry Graeme Anderson (A., P.), James Richard Sumner Anderson (A.), John William Arthur (M.), Allan Robertson Barrowman (A., P.), George Beattie (P., M.), Robert Daniels Bell, M.A. (A., P.), David Blackley (A., P., M), George Thomson Bogle (M.), Robert George Bradford (A.), Forrest Brechin (A., P., M.), Thomas Brodie (P., M), Charles Brown (P., M.), John Brown (A.), George Yuille Caldwell (A., P., M.). Peter Carrick, M.A. (A., P., M.), Robert Buchanan Carslaw, M.A. (A.*, P.*), James Alexander Cowie, B.A., B.Sc. (A., P., M.), John Craig Crawford (P., M.), Thomas Thornton Macklin Dishington (A., P., M.), Hugh M'Millan Donaldson (A.), George Horn Downie (A.), Charles Milligan Drew, M.A. (A., M.), Hugh Harvey Fulton (A.*, P.*), William Harold Gillatt (A., P), James Glover (M.*), David Livingstone Graham (A., P.), John Graham (A.*, P.*), Donald John Gollan Grant (A., P., M.), George Munn Gray (A.*, P.*), Louis Leisler Greig (A., P.), Alexander Robertson Forrest Hay (A., P.), John Cochrane Henderson (A., P.), Arthur Innes (A.*, P.), Alexander Jamieson (A.), Robert Dallas Kennedy (A.), John Kerr (M), George Notman Kirkwood (A., P.), Robert Thomson Leiper (A., P.*, M.), Thomas Symington Macaulay (A., P.), Donald Carmichael M'Cormick (A., P.), Joseph Glaister M'Cutcheon (P.), John Finlay Macdonald (M.), James Boston M'Ewan (A., P.), Tom Duncan M'Ewan (A., P.), Duncan Macfadyen (A., P.), John M'Farlane (A., P.), Robert Macfarlane (A., P), Robert Clark M'Guire (A., P., M.), James M'Houl (A., P.), Milne M'Intyre (A., P., M), Ronald Mackinnon (A., P., M.), David James M'Leish, M.A. (A.*, P.), Roderick MacLeod (M), Norman Smith MacNaughtan (M.), Andrew Brown M'Pherson (P., M.), William Main (A., M.), Andrew Meek (A., P , M.), Peter Millar (A.), Gavin Denholme Muir (P), John Muir (A., P), Macdonald Munro (A , P.), Alexander Harper Napier (A.), George Clement Neilson (A., P.), Thomas Orr (P., M), Howard Henderson Patrick (A., P.), Arthur Geoghegan Paxton (M.), John Clegg Pickup (A., P.), Alexander M'Millan Pollock (M.), Andrew Maclean Pollock (A., P.), James Porter (A., P.), William Murdoch Rae (A., M) Donald Ronald Reid (A., P., M.), Daniel Stevenson Richmond (A), James Watson Richmond (A.), Berkeley Hope Robertson, M.A (A., P.*), Robert Thin Craig Robertson (P.), Campbell Ross (M), John Samson (P.), Lawrence Drew Shaw (A.), Malcolm Alexander Sinclair (P., M.), George Goldie Smith (A., P.*), James Alexander Somerville (P., M.), John Stewart (P.), Norman Burgess Stewart (M), William Craig Stewart (A., P., M), Murray Ross Taylor (A., P. M) William Templeton (A., P.*), James White Thomson (A.*, P.*) Robert Watson (A.), Archibald Cromble West (A., P.), George Henry Wildish (A), George Wilson (P., M.), Robert M Nair Wilson (M.*), James Wynor (P., M.), and Watson Young (A.).

Women.—Jeanie Auld (A), Annie Agnes Baird (A., M.), Annie M'Caig Black (A), Agnes Wallace Cameron (A), Roberta Campbell (A., P., M), Ethel Lily Chapman (A., M.), Jane Hamilton M'Ilroy, M.A., B Sc. (A.), Jane Stark M'Lauchlan (A., P , M.), Alice Wesley Maclean (A., M.) Margaret Walker Millar (M), Jessie Emily Munro (P.), Charlotte Reid Park (A., M), Ethel Jane Mildred Pryce (A., M.), Jane Reid Shaw (A., P), Lily Smellie (A., P.), Elizabeth Taylor Talbert (M), and Annie May Yates (P.)

The following have passed the third professional examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B) in the subjects indicated (P., Pathology; M., Medical Jurisprudence and Public Health :—

Robert Adam (P., M), William Kirkpatrick Anderson (P., M.), Thomas Ballantyne (M), Andrew Farm Bell (M.), Thomas Bennett, M.A. (M), Archibald Grainger Bisset (P., M), Alexander Blair (P., M.), James Campbell Bringan (P., M.), Robert Bruce (M.), Daniel Lyall Carmichael (M.), Alexander Erskine Clark (M.), Andrew Connal (P., M), Hugh Collin Davies (P., M.), Mitchell Innes Dick (P) David Dickie (P., M.), David Garfield Dykes (P., M.), James Eadie (P., M), Cunison Charles Finlator (P., M.), Eric Dalrymple Gairdner (P., M), John Ritchie Gilmour (P.) John Hanson, M.A (P , M.), William Harvey (P.), Leslie Charles Broughton Head (P , M.) Neil M'Coll Hutchison (P., M.) Malcolm Hutton, M A., B Sc. (P *, M), John Muir Kelly (P., M.), Alexander Dingwall Kennedy (M.), Robert Laurie (P., M.), Archibald Leitch (P , M), Thomas Walker Love (P., M), Donald Macaulay (P), James Duff M Culloch (P., M.), David Duncan Fraser Macintyre (P., M), John Matheson Mackellar (P.), Norman Alexander Macleod (P.), James Anthony Macrea (P. M), Harry Somerville Martyn, M.A. (M.), Alexander Matheson, M.A. B Sc., (P *, M.), Spencer Mort (P., M.*), Gavin Muir (P., M.), David Penman (M.), William Rankin, M.A. (P., M), Daniel Falconer Riddell, M.A. (P., M.) Peter Hamilton Robertson (P), Frank Donald Scott (P), William Garrow Shand (P., M.), John Black Stevenson (P) William David Henderson Stevenson, M.A. (P *), William Stewart (P , M.), Arthur William Sutherland, M A. (P., M), John Wilson Sutherland (P.*, M.), Peter Lindsay Sutherland (P * M *), John Restell Thomas (P.), John Turnbull (P.) Joseph Walker M.A. (P), Hugh Fleming Warwick (M.), William Norman West Watson (P , M), Robert Tait Wells, M.A. (P.), John Forrest Weston (P), Griffith John Williams (P., M.), James Wilson (P., M.), Eldred Wright (P , M).

Women.—Mary Charlotte Cameron (P., M.), Jane Campbell (P., M), Jessie Galloway Duncan (M), Kate Fraser, B Sc. (P., M.), Mary Lauchline M Neill (M), Anna Pollock Martin (P. M.), Eliza Jane Miller (P , M.), Isabel Deans Mitchell (P., M.), Margaret Hossack Smart (P , M), Jessie Marie Stewart (P., M.).

* Passed with distinction in the subjects indicated.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin*: Professor Beckmann of Leipsic has been appointed to the chair of Pharmaceutical Chemistry, with which is combined the charge of the newly-established Institute for Pharmaceutical Chemistry —*Budapest*: Dr. Emerich Havas, *privat docent* of Dermatology, has been promoted to an Extraordinary Professorship. Dr. Krompecher has been recognised as *privat-docent* of Physiology.—*Freiburg*: Dr. Hugo Sellheim, *privat-docent* of Midwifery, has been promoted to an Extraordinary Professorship.—*Halle*: Dr. H. Winternitz has been recognised as *privat-docent* of Medicine. —*Heidelberg*: Dr Alexander Nehrkorn has been recognised as *privat-docent* of Surgery.—*Innsbruck*: Dr. Max von Vintschgau, Professor of Physiology, is about to retire —*Lemberg*: Dr. Roman Rencki has been recognised as *privat-docent* of Medicine.—*Munich*: Professor J. von Bauer has been appointed to succeed his late father-in-law Professor von Ziemssen, both in the chair of Medicine and in his hospital appointment. For the vacancy thus caused in the second chair of Clinical Medicine the following names have been selected by the Medical Faculty: (1) Professor Friedrich Müller of Basle; (2) Professor Krehl of Tübingen; and (3) Professor Stintzing of Jena.—*Philadelphia (Polyclinic)*: Dr. John H. Gibbon has been appointed to the chair of Surgery in succession to Dr. Morton, resigned.—*Prague (Bohemian University)*: Dr. Scherrer has been promoted to an Extraordinary Professorship of Infantile Diseases.—*Rome*: Dr. Attilio Bonanni has been recognised as *privat-docent* of Physiological Chemistry.—*Strasburg*: Dr. Paul Manasse, *privat-docent* of Otology, has been promoted to an Extraordinary Professorship.—*Tübingen*: Dr. L. Krahl, Professor in the University of Greifswald, has been appointed to the chair of Clinical Medicine in succession to the late Professor von Liebermeister.—*Turin*: Dr. Edmondo Trombetta has been recognised as *privat-docent* of Ophthalmology.—*Vienna*: Dr. Theodor Escherich, Professor in the University of Graz, has been appointed to the chair of Children's Diseases in succession to the late Professor von Widerhofer.

Hospital Saturday.—The Council of the Hospital Saturday Fund will hold its annual special collection in the workshops and business houses of the metropolis on Saturday, Oct. 11th. At the quarterly meeting of the board of delegates held at the central offices, Gray's Inn-road, W.C., on April 5th it was announced that during 1901 28,207 letters of recommendation to the medical charities had been issued upon the application of the collectors. The receipts from the workshops, &c., from Jan. 6th to March 15th, amounted to £2170 14*s.* 7*d.*, as compared with £2387 at the corresponding period of last year. The March number of the "Hospital Saturday Fund Journal" among other interesting matter contains an admirable paper by Dr. T. D. Acland on "Our Fight against Small-pox, or Common Sense and Vaccination."

Donations and Bequests to Hospitals.—By the will of Miss Anne B. Miles of Highgate £3000 are bequeathed to the Mission to Deep Sea Fishermen for a hospital mission ship to be called the Joseph and Sarah Miles Mission Ship. To the North-West London Hospital, the London Fever Hospital, the Great Ormond-street Hospital for Sick Children, the Cripples' Home in Marylebone, the Mount Vernon Hospital for Consumption, the Ventnor Hospital for Consumption, and the Royal Sea-bathing Infirmary at Margate £100 each are given, and £50 to the North London Nursing Association, Upper Holloway.—Mr. Arthur Ocran Crooke of St. Margaret's-on-Thames has bequeathed to his trustees £20,000 in trust for such hospital or hospitals in the counties of London and Surrey and convalescent homes in connexion with such hospitals as the trustees may choose.—By his will Mr. O. Sellers of York has bequeathed £1050 to the York County Hospital and £500 to the York Dispensary.—Mr. W. J. Clutton of York has left by his will £1000 to the York County Hospital.

The Fernley Observatory.—In his report for the year 1901, Mr. Joseph Baxendell, meteorologist to the Southport Corporation and director of the Fernley Observatory, supplies a variety of interesting details relative to the working of some of the instruments, and in particular of Dines's pressure-tube recording anemometer, Dines's non-oscillating pressure plate maximum anemometer, Baxendell's recording anemoscope, and Halliwell's float-pattern self-recording rain gauge. The last-named instrument has been found to furnish a faithful and distinct record alike of the heaviest tropical downpour and of a wet fog or misty drizzle. In order that snow which has fallen may be melted and for the purpose of preventing damage to the instrument from frost it can be warmed by a Notkin carburetter which will continue to act although not attended to for a week or even a month at a time. The highest temperature registered at the observatory during the year was 87·2° F. on July 20th; the lowest was 21 0° on Jan. 9th and also on Dec. 22nd. The heaviest fall of rain on any one day was 1·76 inches on Nov. 11th.

International Congress of Americanists.—It is announced in the April number of *Man*, a journal published by the Anthropological Institute, that the thirteenth session of the International Congress of Americanists will be held in the American Museum of Natural History, New York, from Oct. 20th to the 25th, 1902. The subjects to be discussed by the congress relate to the origin, distribution, physical characteristics, &c., of the native races of America and the history of the early contact between America and the Old World. All persons interested in the study of the archæology, the ethnology, and the early history of the two Americas may become members of the congress by signifying their desire to the general secretary of the commission of organisation, Mr. M. H. Saville, American Museum of Natural History, New York, together with a remittance of $3. Communications may be oral or written, and in French, German, Spanish, Italian, or English.

Death of a Medical Centenarian.—The March number of the *Pacific Medical Journal* states that Dr. Henry Carson, of Forest City, Pennsylvania, has died at the age of 108 years, and that he practised his profession up to last October.

Royal Alexandra Hospital, Rhyl.—It is announced that the Prince and Princess of Wales will on May 12th visit Rhyl for the purpose of opening the new buildings of the Royal Alexandra Hospital, the foundation-stone of which was laid by Her Majesty Queen Alexandra in 1894. The cost is estimated at over £40,000 and £2500 are still required to complete this estimate. Some 700 patients are received each year at the hospital, mostly from the large towns of Staffordshire, Cheshire, Shropshire, Warwickshire, Lancashire, and other English counties,

Gloucester Infirmary.—A special appeal, signed by the Earl of Ducie (lord lieutenant of the county) and Colonel Curtis-Hayward (chairman of the committee), has just been issued on behalf of the Gloucester General Infirmary and Eye Institution which needs the sum of £10,000 to bring it up to the needs of modern requirements. The Earl of Ducie heads the appeal with a subscription of £500; Mr. W. E. Price gives £300; Lord Fitzhardinge gives £200; and 14 other subscribers give £100 each.

Bristol Eye Hospital.—The annual meeting of the subscribers to this institution was held on March 26th, under the presidency of the Right Hon. Lewis Fry. The ninety-first annual report, which was read, stated that 5503 new out-patients were treated during 1901, and that the in-patients admitted to the hospital numbered 402. The financial statement showed that the expenditure exceeded the income by nearly £350, and that there still remained a debt of £1900 on the recent extension of the hospital which was carried out at a cost of £7300.

Presentations to Medical Practitioners.—At Barnstaple on March 24th, Mr. Mark Jackson, M.D. R.U.I., M.R C.S. Eng., L.S.A., who is leaving Barnstaple, where he has been medical officer of health for the past 15 years, was presented by the residents with a cabinet of table silver, a silver kettle, and an album bearing the names of the subscribers, as a mark of respect and esteem. The members of the Barnstaple Congregational Church have presented Dr. and Mrs. Jackson with a silver inkstand.—The members of the Princetown (Devon) Branch of the St. John Ambulance Association, on March 21st presented Mr. Daniel Brough, M.B., C.M. Edin., L.R.C.P. Lond., M.R.C.S. Eng., with a silver-mounted inkstand as a mark of appreciation for his services as honorary lecturer.—Mr. George Henry Temple, M.B., C.M. Edin., of Weston-super-Mare, who recently rendered assistance to a police constable in the arrest of a violent prisoner, was on March 23rd presented with a silver cigarette case, subscribed for by the local members of the constabulary, in recognition of his valuable services on that occasion

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Beer Bill.

In connexion with the order for the second reading of the Beer Bill Mr. Flower has given notice that he will move as an amendment: "That this House declines to proceed with the consideration of a Bill interfering with freedom in the manufacture of beer in this country which, whilst it imposes upon the scientific development of British brewing industries arbitrary restrictions that cannot be enforced upon foreign competitors, in no way provides safeguards for the public health or secures for consumers a guarantee as to the purity of the materials employed."

The Midwives Bill.

The consideration of this Bill as amended by the Grand Committee has been put down for Wednesday, June 4th, when there is considerable possibility of its being taken.

HOUSE OF COMMONS.

TUESDAY, APRIL 8TH.

The Use of Lead Pills.

Mr. COGHILL asked the Home Secretary whether his attention had been called to an inquest held by the coroner for North-West Staffordshire, on March 18th, on a married woman residing at Porthill, when the coroner, in summing up, stated that it appeared that the deceased was a milliner and had never been employed in occupations likely to produce lead-poisoning, and consequently could not have got this condition in the course of her trade; that it could not be difficult to find out where this lead was obtained; and that if this had been done and the person who supplied it knew for what purpose he would find himself charged with manslaughter at least; and, in view of the fact that the jury returned a verdict to the effect that death was due to lead poisoning brought about by deceased taking pills for a certain purpose, whether he would cause inquiries to be instituted as to the person who supplied the deceased with the lead pills.—Mr. RITCHIE said: I understand that active inquiries have been made and that no clue has been obtained to trace the person who supplied the pills.—Mr. COGHILL: May I ask the right hon. gentleman whether in the course of the inquiries made it has been found that this practice is at all common.—Mr. RITCHIE: The inquiries have not been directed to that general question but to the question of where the particular pills were bought.

Equipment of Military Hospitals in India.

Mr. WEIR asked the Secretary of State for India whether arrangements could be made for the military hospitals in India to be provided with surgical instruments of modern pattern, and would surgical instruments with wooden handles either be withdrawn or refitted with metal handles.—Lord GEORGE HAMILTON said: I am informed that all instruments sent to India in recent years have metal handles, but I will inquire more fully into the matter and if there is any reason to suppose that a large proportion of the surgical instruments now in use in India are not of the most approved pattern the Government of India will, I have no doubt, be anxious to replace them with as little delay as possible.

The Small-pox Epidemic in London.

Mr. BARTLEY asked the President of the Local Government Board whether he could state approximately the cost which the present epidemic of small pox had involved in the London area up to March 31st last.—Mr. LONG replied: I understand that the epidemic has involved an expenditure of about £250,000 on the part of the managers of the Metropolitan Asylums Board during the half year to the end of March last. This amount includes a sum of £225,000 in respect of special expenditure in connexion with small-pox accommodation and transport. I have no information at present as to the amounts expended by boards of guardians and other local authorities in London in connexion with the epidemic. There may be further information later and if the hon. Member moves for a return I shall be prepared to grant it.

Vaccination Statistics.

Mr. CORRIE GRANT asked the President of the Local Government Board (1) whether he had observed in the weekly returns of the Registrar-General that an infant, born on the hospital ship *Atlas* on March 1st, was vaccinated on that day and died from small-pox on the 12th, and that many other similar cases occur in the returns; (2) whether in view of these results he would consider whether the vaccination of such children after infection should be abandoned; and (3) as in several cases of death from small pox after vaccination the dates of vaccination were omitted and the words "vaccinated during the incubation period" or "vaccinated only after infection" were employed, whether he would direct the hospital authorities to supply exact particulars to the Registrar General, so as to obtain uniformity in these statistics.—Mr. LONG replied: As regards the first paragraph the answer is in the affirmative. With respect to the second I could not undertake to recommend the course suggested. As to the third paragraph I have communicated with the Registrar-General, who states that it is impossible to obtain uniformity in all cases, and that under the circumstances he considers that the terms employed are the best that can be devised.

The Supply of Government Lymph.

Mr. BARTLEY asked the President of the Local Government Board whether he could state what progress had been made in the supply of Government lymph; whether the Local Government Board had been able to overtake the demand for it; and whether any arrangements had yet been made to supply private practitioners as well as the public vaccinators with Government lymph for primary and secondary vaccination at about cost price.—Mr. LONG replied: I am glad to say that since the early part of last month I have been able to meet all the demands made by public vaccinators for lymph not only for primary vaccinations but also for revaccinations. As regards the last part of the question I have carefully considered the matter, but I regret that I have not seen my way at present to comply with the suggestion of my hon. friend.

BOOKS, ETC., RECEIVED.

BERGMANN, J. F., Wiesbaden (F. BAUERMEISTER, 49, Gordon-street, Glasgow).

Uber die Ätiologie des Carcinoms, mit besonderer Berücksichtigung der Carcinome des Scrotums, der Gallenblase, und des Magens. Von Dr. Gustav Futterer, Professor der Pathologie an der Universität in Chicago. Price M. 4, or 4s.

Arbeiten aus der Pathologisch Anatomischen Abtellung des Königl. Hygienischen Instituts zu Posen. Von Professor Dr. O. Lubarsch. Price M. 9, or 9s.

Vier Vorlesungen aus der Allgemeinen Pathologie des Nervensystems, gehalten vor dem Royal College of Physicians of London, am 19., 21., 26., und 28. Juni, 1900, von Frederick W. Mott, M.D. Lond., F.R.S. Übersetzt von Dr. Wallach. Mit einem Vorwort von Professor Dr. L. Edinger. Price M. 2.80, or 3s.

Die Berufskrankheiten des Ohres und der Oberen Luftwege. Von Dr. med. Friedrich Röpke, in Solingen. Price M. 5, or 5s.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

ANGUS, H., M.D. Aberd., has been appointed Medical Officer of Health to the Bingley Urban District Council.

BENNETT, C. J., M.R.C.S., has been re-appointed Medical Officer of Health to the Chapel-en-le-Frith Rural District Council.

BURTON, H., L.R.C.P. Irel., M.R.C.S., has been re-appointed Medical Officer of Health to the Marple District Council.

BYTHELL, W. J. S., B.A., M.B. Ch.B., has been appointed Junior Anæsthetist to the Manchester Royal Infirmary, vice J. Turville Smith, resigned.

CLAPHAM, LUCY B., M.B. Lond., has been appointed Obstetric Physician to the New Hospital for Women, Euston road, and Assistant Anæsthetist to the Royal Free Hospital.

Cope, Ricardo, M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon to the Dorset County Hospital, Dorchester.

Dalby, Augustus William, L.R.C.P., L.R.C.S. Edin., has been re-appointed Medical Officer of Health of the Frome (Somerset) Rural District.

Fry, W. W. B., M.B., M.S. Edin., has been re-appointed Medical Officer of Health to the Builth Rural District Council.

Greenwood, G. S., M.R.C.S., L.R.C.P. Lond., has been re-appointed Medical Officer of Health to the Ossett Corporation.

Harman, N. Bishop, M.A., M.B. Cantab., F.R.C.S. Eng., has been appointed Ophthalmic Surgeon to the Belgrave Hospital for Children, vice Treacher Collins, resigned.

Harnett, Charles J., M.D., L.R.C.P. Lond., M.R.C.S., has been appointed Honorary Assistant Visiting Surgeon to the Royal Sea Bathing Hospital, Margate.

Hodgson R. E., M.R.C.S., L.R.C.P. Lond., has been appointed Senior Resident Surgeon to the Royal Sea Bathing Hospital, Margate.

Jeffery, H. Foster, M.B., Ch.B. Vict., has been appointed Honorary Surgeon to the Bury Infirmary and Police Surgeon for Heywood.

Kempe, C. M., M.R.C.S., L.S.A., has been re-appointed Medical Officer of Health to the Shoreham Urban District Council.

Liston, Mary F., M.B., B.S. Glasg., has been appointed Junior Assistant Medical Officer to the Govan Parish Council.

Marshall, Frank E., M.B., Ch.B. Vict., L.S.A., has been appointed Honorary Surgeon to the St. George's Hospital for Diseases of the Skin, Liverpool.

Mather, R. O., L.R.C.P., L.R.C.S. Edin., has been re-appointed Medical Officer of Health to the Billinge Urban District Council.

Prior, Percival Underdown, M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer to the Destitute and Aborigines in the district of Penola, South Australia.

Verco, W. A., M.B., Ch.B. Adel., has been appointed Assistant Gynæcologist to the Adelaide Hospital, South Australia.

White, Margaret M.B. Melb., has been appointed House Surgeon to the Children's Hospital, Adelaide, South Australia.

Wilson, T. G., M.B., Ch.M. Syd., has been appointed Assistant Gynæcologist to the Adelaide Hospital, South Australia.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Bethnal Green Infirmary.—Third Assistant Medical Officer. Salary £100 per annum, with apartments, board, and washing.

Biggleswade Rural District Council.—Medical Officer of Isolation Hospital and Small-pox Hospital. Salary £60 a year, additional fee of £5 5s. a week if and when patients are treated in the small-pox hospital.

Birmingham and Midland Hospital for Skin and Urinary Diseases, John Bright-street, Birmingham.—Surgical Assistant. Honorarium 50 guineas per annum.

Birmingham Workhouse Infirmary.—Assistant Resident Medical Officer. Salary £100 per annum, with apartments, rations, attendance, &c.

Bradford Royal Infirmary.—Dispensary Surgeon, unmarried. Salary £100 per annum, with board and residence.

Brentford Union Workhouse and Schools, Isleworth.—Assistant Medical Superintendent, unmarried. Salary £120 per annum, with apartments, rations, washing, &c.

Bridgwater Infirmary.—House Surgeon. Salary £80 a year, with board and residence

Cambridgeshire, etc., Lunatic Asylum, Fulbourn, near Cambridge.—Assistant Medical Officer (unmarried). Salary £150 per annum, with board, lodging, and attendance.

Central London Sick Asylums at Cleveland-street or Hendon.—First Assistant Medical Officer. Salary £120 per annum, with board and residence.

City of Nottingham Parish Infirmary.—Assistant Medical Officer. Salary £160 per annum and rooms.

Cornwall County Asylum, Bodmin.—Junior Assistant Medical Officer, unmarried. Salary £120, rising to £150, with board, apartments, &c.

Cosford Union, Suffolk, Bildeston District.—Medical Officer and Public Vaccinator. Salary £72 per annum (exclusive of fees approximating to £76 per annum).

Cosford Union Workhouse, Suffolk.—Medical Officer. Salary £50 per annum, with fees.

Crewe Borough.—Medical Officer of Health. Salary £350 per annum.

Croydon County Borough Lunatic Asylum, Warlingham, Surrey.—Medical Superintendent. Salary £450 per annum, with unfurnished house, fuel, light, washing, &c.

Cumberland and Westmorland Asylum, Garlands, Carlisle.—Junior Assistant Medical Officer, unmarried. Salary £130, rising to £150 per annum, with board, lodging, &c.

Durban, Natal, South Africa.—Medical Officer of Health. Salary at rate of £750 per annum.

Durham County Asylum.—Junior Assistant Medical Officer wanted. Salary £150, rising to £180 a year, with apartments, board, laundry, and attendance.

Durham County Hospital.—House Surgeon and Assistant House Surgeon. Salary of Senior House Surgeon £100, Junior £65, with board and lodging in each case.

Fisherton Asylum.—Assistant Medical Officer, unmarried. Salary £150 per annum, with board, lodging, and washing.

Grove Hall Asylum, Bow, London, E.—Junior Assistant Medical Officer. Salary at rate of £120 a year, with board, apartments, attendance, and washing.

Guy's Hospital.—Demonstrator of Bacteriology and Bacteriologist. Salary about £180, rising to £200 per annum.

Hospital for Sick Children, Great Ormond-street, London, W.C.—House Surgeon, unmarried, for six months. Salary £20, washing allowance £2 10s., with board and residence. Also Medical Registrar. Honorarium 50 guineas a year.

Kent and Canterbury Hospital.—Surgeon.

Leeds General Infirmary.—House Physician for six months. Board, lodging, and washing provided.

Leeds Hospital for Women and Children.—House Surgeon, non-resident, for six months, eligible for renewal. Salary at rate of £125 per annum.

Lincoln Hospital for the Insane, The Lawn.—Assistant Medical Officer. Salary £100 a year.

Liverpool, County Asylum, Rainhill.—Assistant Medical Officer, unmarried. Salary £150 per annum, with prospect of increase, with apartments, board, attendance, and washing.

Liverpool Stanley Hospital.—Third House Surgeon. Salary £70 per annum, with board, residence, and washing.

London County Asylum, Horton, near Epsom, Surrey.—Junior Assistant Medical Officer. Salary £150 per annum, with board, furnished apartments, and washing. Also Dispenser. Salary £140 per annum, rising by £10 a year to £150, with dinner daily.

London Temperance Hospital, N.W.—Assistant Resident Medical Officer for six months. Honorarium at rate of 50 guineas per annum, with board and residence.

Manchester Southern and Maternity Hospital.—Resident House Surgeon. Honorarium £50 per annum and board.

Newcastle-on-Tyne Dispensary.—Visiting Medical Assistant. Salary £160, rising to £180.

Norfolk and Norwich Hospital.—House Surgeon, unmarried. Salary £80 per annum, with board, lodging, and washing.

Nottingham General Dispensary.—Assistant Resident Surgeon, unmarried. Salary £160 per annum, increasing by £10 every year, with apartments, attendance, light, and fuel.

Oldham Infirmary.—Senior House Surgeon. Salary £100 per annum, with board, residence, and washing.

Parish of Hammersmith Temporary Infirmary, Ducane-road, Wormwood Scrubs, S.W.—Visiting Medical Officer. Salary £50 per annum.

Poplar and Stepney Sick Asylum at Bromley, Middlesex, E. Second Assistant Medical Officer. Salary £100 per year, with rations, apartments, and washing.

Public Dispensary, 59, Stanhope-street, Clare Market.—Resident Medical Officer, unmarried. Salary £105 per annum, with furnished apartments, coals, and gas.

Stoke-on-Trent Infectious Diseases Hospital, Bucknall.—Resident Assistant Medical Officer. Salary £80 per annum, with board, residence, and washing.

Teignmouth Hospital, S. Devon.—House Surgeon. Salary £70 a year, with board, lodging, and washing, and allowance of £6 in lieu of stimulants.

Unbridge Wells General Hospital.—House Surgeon, unmarried. Salary £100 per annum, with board, apartments, and attendance.

Wallasey Dispensary and Victoria Central Hospital, Liscard.—House Surgeon, unmarried. Salary £100, with board and residence.

West End Hospital for Nervous Diseases, Welbeck-street, Cavendish-square, W.—Honorary Dental Surgeon.

West London Hospital, Hammersmith-road, W.—Honorary Officer in charge of the X Ray Department.

West Norfolk and Lynn Hospital, King's Lynn.—House Surgeon. Salary £100 per annum, with board, residence, and washing.

Births, Marriages, and Deaths.

BIRTHS.

Harrison.—On April 5th, at 320, Humberstone-road, Leicester, the wife of L. K. Harrison, M.B. Cantab., of a son.

Holden.—On April 6th, at Castle-hill, Reading, the wife of George Herbert Rose Holden, M.A., M.D. Cantab., of a son.

Potts.—On March 17th, at the Infirmary, Cambridge-road, Bethnal Green, the wife of W. J. Potts, M.D. Lond., of a daughter.

Ransome.—On April 6th, at Bungay, Suffolk, the wife of Gilbert H. Ransome, M.R.C.S., L.R.C.P. Lond., of a daughter.

MARRIAGES.

Collinson—Clarke.—On April 3rd, at St. Alkmund's church, Derby, by the Rev. A. E. Hunt, M.A. (vicar), assisted by the Rev. S. E. Collinson (the bridegroom's brother), Frederick William Collinson, M.D., of Preston, to Clara, daughter of the late Thomas Clarke, of Derby.

Henry—Farr.—On the 5th April, at Immanuel Church, Streatham-common, by the Rev. H. F. S. Adams, M.A., vicar, George Nicol Henry, M.B., fourth son of the late Andrew Henry, of Macduff, N.B., to Mary Louise, youngest daughter of the late Dr. George Frederick Farr, of Kennington and East Twickenham, and Mrs. Farr of Oakdale-road, Streatham.

Ormerod—Tyssen.—On April 8th, at St. Patrick's, Hove, by the Rev. Arthur Sutton, rector of Brant Broughton, Lincolnshire, cousin of the bride, assisted by the Ven. the Archdeacon of Lewes and the Rev. T. Rowland Hall, senior curate of the church, Ernest William Ormerod, M.D., elder son of the late Edward Latham Ormerod, M.D., F.R.S., to Janet Clara, eldest daughter of the Rev. Ridley Daniel-Tyssen, incumbent of St. Patrick, Hove.

Prior—Mallalieu.—April 3rd, at Christ Church, Glodwick, Oldham, by the Rev. Howard Chadwick, M.A., James Prior, M.R.C.S., L.R.C.P., of Brookroyd, Heckmondwike, to Amy, younger daughter of the late William Mallalieu of Oldham.

Rutherford—Mitchell-Withers.—On April 10th, at St. Michael's, West Retford, by the Rev. Canon Gray, M.A., assisted by the Rev. C. V. Collier, F.S.A., Allen Freer Rutherford, M.B. Edin., second son of Dr. James Rutherford of Dumfries, N.B., to Beatrice, younger daughter of the late J. B. Mitchell-Withers, of Parkhead, Sheffield.

DEATHS.

Chilton.—On April 2nd at Bristol, Reginald Horace Chilton, M.R.C.S., L.R.C.P. Lond., aged 31 years.

Fox.—On April 2nd, at Brislington House, near Bristol, Bonville Bradley Fox, M.D. Oxon., aged 49 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

SYDENHAM AND THE OPEN AIR TREATMENT OF PHTHISIS

To the Editors of THE LANCET

SIRS —In the writings of Sydenham is a passage very like that quoted in THE LANCET of March 29th p 898 in allusion to Dr Bollington s work. It is apparent from it that his advocacy can be claimed for the open-air treatment of phthisis I transcribe from Pechey's translation of Sydenham s works published in 1740 He is proclaiming the advantage of horse-exercise in hepatic (?) disorder and *proceeds*:—

> Nor is this kind of exercise more beneficial to hypochondriacal people than to those that are in a Consumption whereof some of my relations have been cured by riding long journeys by my advice; for I knew I could not cure them better by medicine; of what value soever *or by any other method* *Nor is this remedy proper only in* small indispositions accompanied with a frequent cough and leanness but also in Consumptions that are almost deplorable, when the looseness above mentioned accompanied the night-sweats which are wont to be the forerunners of death in those that die of a Consumption To be short, *how deadly soever a Consumption is and is said to* be two-thirds dying of it who are spoiled by chronical diseases yet I sincerely assert that Mercury in the French Pox and the Jesuits Bark in Agues, are not more ffectual than the exercise above mentioned in Airing a Consumption if the sick be careful and the *sheets be well-aired and that the journeys are long enough* But this must be noted that those who are past the flower of their age must use the exercise much longer than those that have not yet arrived to it; and this I have learned by long experience which scarce ever failed me And though riding on horseback is chiefly beneficial to *people that have a Consumption, yet riding in a coach* is sometimes very beneficial "

Clearly the one thing common to riding and to driving is open-air exercise while Sydenham s injunction that the sick be careful and the sheets be well-aired" anticipates the regimen of the modern sanatorium *I am Sirs yours faithfully*

Leek, April 3rd 1902. DAVID A ALEXANDER.

P S —Is the Government making any special provision for soldiers n South Africa who have contracted phthisis during the rigors of the campaign? He has a very poor chance of recovery who comes home after his discharge to the closer air of the houses of our reeking towns.

A WARNING

To the Editors of THE LANCET

SIRS,—I think it might save other medical men from being victimised if you were to issue a warning in THE LANCET against a man giving the name of Captain Davys who has succeeded in borrowing money from me and from the wife of another medical man in this neighbourhood. His story is that he wants the medical man on whom he is calling to attend his wife in her approaching confinement that they are coming to an address quite close at hand on the following day but that at present they are living in the country He hopes the doctor will be able to call and see his wife the following afternoon as she is afraid of being upset by the journey He himself has ridden up on his bicycle from where they are living in the country and (quite incidentally) he has come away without any money It does not matter of course, as he has his bicycle, but it is awkward not being able to get anything to eat as he knows no one in London. He has made this story profitable in at least two doctors houses in Kensington and I hear that a very similar tale has been tried in other parts of London

I am Sirs yours faithfully

Kensington April 7th, 1902. P

REVOLVING SHELTERS

To the Editors of THE LANCET

SIRS —I shall be obliged if any of your readers can give me the names and addresses of makers of revolving shelters constructed of wood and glass I am Sirs yours faithfully

ROBERT MACKINLAY

Ashbank, Newton Mearns Renfrewshire April 7th, 1902.

THE TREATMENT OF SMALL-POX.

A CORRESPONDENT in view of the present prevalence of small pox forwards to us some interesting details of the methods of treatment found useful in the Sheffield epidemic of 1887-1888. Some 400 cases were *treated* at the patients *own homes*. *Diaphoretics* were found to be contra indicated after the second day and bromides were found useless to relieve the headache. On the other hand a brisk saline purge was found of great use. With regard to the local treatment of the eruption the following plan gave good results "Each pustule, not only on the face but on the limbs and body also was swabbed over with some antiseptic. At that time Little s phenyl was supplied by the local sanitary authority and this was used but izal or carbolic oil would do equally as well. A large needle was then passed through each pustule and the pus evacuated As many pustules as possible were thus dealt with on the eighth ninth and tenth days of the disease. The results in most cases were most satisfactory. Particularly in patients and especially in young subjects where many pustules occurred on the palmar and plantar surfaces of the hands and feet respectively and where such symptoms as insomnia and great nervous prostration were prominent, I found the treatment give great relief and natural sleep usually followed the general condition being also much improved." It was necessary to treat many cases of small pox delirium. If two minims of croton oil were rubbed on the base of the patient s tongue very free purgation quickly followed and within two hours the patient was found to be perfectly quiet

A SANITARY POWDER PUFF

THE powder-puffs commonly used by hairdressers evidently present facilities for the transmission of skin affections and other contagious diseases from one customer to another on account of the readiness with which clippings of hair loose epithelium and other *tonsorial débris adhere to their surfaces A powder-puff can hardly* be sterilised but an easy and satisfactory way of avoiding all risk is to use a new one each time The Odourless Retentive Disinfecting Cloth Company of 96 Leadenhall-street, London E.C supplies an article very suitable for this purpose, consisting of a disc *of stiff coloured paper about two inches in diameter faced on one* side with a thin layer of cotton wool We understand that the price of these sanitary powder puffs is so small that on financial grounds a barber can have no inducement to use them over and over again By this precaution, together with those described in THE LANCET of April 5th p 983 *the risk of contagion in hairdressers shops will be* reduced to a minimum

PROPOSED MEMORIAL TO THE LATE SURGEON-GENERAL W NASH A.M.S

THE DUPLEX ROTARY BOTTLE AND DECANTER WASHER

MESSRS G RESTALL AND CO of 57 Park-road Regent s Park London N W have submitted to us an ingenious and simple device for the cleaning of bottles decanters, &c. It consists practically of a screw *drill attached at its top end to a shelf by means of a spring* The drill rotates rapidly by merely grasping a bobbin with a thread corresponding to that of the drill and moving it rapidly up and down It is the principle of the Archimedean screw but reversed In the place of a drill bit the brush is fixed or a double hoop of stout wire when the effect of a whisk is required The apparatus works well and very effectively removes the dirt in bottles or flasks of whatever shape they may be. It is particularly well adapted we have found for cleaning bottles which have contained milk A clean milk bottle is of course, of the greatest importance, but it is *not easy thoroughly* to cleanse a narrow necked bottle such as that in which milk is sterilised and which contains adherent and stale milk sediments The apparatus may be applied to a variety of purposes and can claim to be in the strictest sense a real sanitary accessory

RADCLIFFE *v* PRICE

To the Editors of THE LANCET

SIRS —I read with much interest your leading article in THE LANCET of March 29th p 902, on Radcliffe *v* Price, and I quite agree with your views as to the matter of costs in the case. I think the decision on this point, at *least, is a very unjust one and I trust steps will be taken to* set it aside. I wonder what Mr Justice Swinfen Eady would say to members of his own profession who very cleverly got themselves inserted in wills as residuary legatees " They have plenty of time to wind up the estate and it is some time before their share can be estimated and then for various and obvious reasons, it is hardly likely that any inquiry will be instituted. I know a case where something like £20 000 were obtained in this way by a respectable solicitor and where there was no other connexion than that as between lawyer and client. I am, Sirs yours faithfully

SADDLE SORENESS —VARICOSE VEINS

To the Editors of THE LANCET

SIRS —A warm comfortable, well-fitting perforated saddle-cloth made of thick felt is a great addition to a suitable cycle saddle such as Brook s saddles generally are, and tends to prevent saddle soreness, which I have also found I thought further prevented if going for a long ride say 50 miles by wearing ordinary bathing drawers which proved no inconvenience and were worn with great comfort when going to Oxford on my cycle with my son last October I was led to wear the drawers owing to being somewhat corpulent (I measure in girth, measuring round the umbilicus 42½ inches) and I found the drawers which reached well up to the navel a great support to the abdominal muscles and certainly they prevented the flatulency and dyspepsia that a long ride is apt to produce. I rode the whole distance, stopping at Winchester on the first night, with ease, and also rode most of the return journey on my cycle (after staying three days enjoying the sights of the classical city) with great comfort and no saddle soreness. It occurred to me that the information might be useful to your readers.

You have, Sirs, in a leading article on March 22nd, p. 833, usefully directed attention to varicose veins and Mr. Pearce Gould's excellent and comprehensive lecture. I think many of your readers who are cyclists, and who are often asked if a youth who suffers from varices may ride, may perhaps, be glad to know that I have found cycling most beneficial for varicose veins, from which I have suffered all my adult life, and sometimes severely, having had three attacks of phlebitis in my left leg, the first after a long row from Hammersmith to Kingston in 1865. Previously to my marriage in 1866 I consulted Mr. T. W. Nunn, then surgeon to the Middlesex Hospital, as to whether he would advise Mr. Lee's operation for me, at that time the operation not being as successful as it is now. After careful examination, Mr. Nunn did not advise operative treatment but suggested that I should wear elastic stockings which for many years I generally did, especially on the left leg, and I had no further inconvenience from them until after a serious illness with very high temperature in 1882, sometimes 105° F. (not rheumatic). My temperature very easily goes up. I have more than once gone about seeing my patients with a temperature of 103°. I remember once calling my eldest son's attention, then a medical student, to this rather *interesting fact when we were in Antwerp and were going before breakfast* to the swimming baths—"Now, look here, my temperature is now 103° [verified by thermometer]. You will find after my swim [the water was very cold] it will go down to 98° or 99°"; and so it did, and did not rise as high again. I was not feeling well, of course, although no one would for a moment have thought I had a temperature of 102° or 103°, but after each morning swim it was lower and within a week remained normal. I had a third attack of phlebitis in 1898 and suffered a great deal of pain, especially in going down to Hastings, but this time the inflammation subsided by sea air, rest, and iodide of lead and opium lotion without forming abscesses, and on recovery from illness the veins were *in statu quo antea*. After my residence here I did not keep carriages and learnt to cycle, using my machine like a hack and deriving more pleasure and health from its perpetual and daily use when fine than I did from my horses and I have now no varicose veins, at least no nodes—merely slight dilatation of the superficial veins of the left leg. Cycling has cured them.

I am, Sirs, yours faithfully,

FREDK. H. ALDERSON, M.D. St. And.

West Bournemouth, April 5th, 1902.

INCONTINENCE OF URINE.

To the Editors of THE LANCET.

SIRS,—Your correspondent "S. S. B." will find the following useful: sodii benzoas, 10 grains; sodii bicarb., 10 grains; tr. hyoscyami, 30 minims; barley water to one ounce, to be taken every night two hours before going to bed.

I am, Sirs, yours faithfully,

Windsor, April 5th, 1902. W. B. HOLDERNESS.

To the Editors of THE LANCET.

SIRS,—The following extract from my note-book, copied from a medical paper about 13 years ago, has given excellent results: "M. Perrett recommends giving to children from five to eight years of age one to two grammes of antipyrin every evening—one part taken at 7 and the other at 9 o'clock. Treatment continued eight days, then a week's respite, and again administered. Two weeks of treatment is generally sufficient for a case." I may add that in my experience the older the boy the more successful the result.

I am, Sirs, yours faithfully,

Batley, Yorks, April 4th, 1902. JOHN H. WOODS, L.R.C.P. Irel.

To the Editors of THE LANCET.

SIRS,—I believe that in many cases of boys who wet the bed the habit is due to masturbation, and this should be carefully looked for. It is also advisable that the amount of liquid taken in the evening should be restricted as much as possible.

I am, Sirs, yours faithfully,

April 9th, 1902. G. F. B.

THE ANTI-VACCINATIONIST IN HIS TRUE COLOURS.

WE have received a most interesting communication from a gentleman named W. D. Stokes, who lives at 14, Waterloo-place, Brighton. Mr. Stokes is of opinion that the "vast majority of the community are unconverted and are yet sceptical as to the efficacy of the operation of vaccination to prevent, or even to mitigate, an attack of small-pox." Mr. Stokes is good enough to forward us a "bill" which he hopes "may be of some service in enlightening you touching the subject in question." We must allow that Mr. Stokes's bill has given us some information of which we were quite ignorant. Here are some of the things he tells us. "It is the opinion of honest physicians that vaccination is causing the death of 100,000 people in the United Kingdom every year." "As the late Royal Commission did not give to the Government a true statement respecting the effects of vaccination, *some honest doctors* say that the great majority of the members of the Royal Commission deserve penal servitude for the remainder of their lives, for they have been the means of keeping up the wholesale murderous practice." "We have the testimony of 232 medical men that vaccination has within their own experience caused 55 different diseases ...... including internal diseases, ulcerated stomach, liver disease, consumption, cancer ...... inflammation, paralysis, ricketts (*sic*), scarlatina, leprosy, and many other diseases. ...." Mr. Stokes has the courage of his opinions, such as they are. Like the public-house orator we are not going to argue with him, we are going to tell him, and we will do so in his own words: "All such dishonest, untruthful, deceitful, wicked people (doing differently from that which they would be done by) will find themselves at the left hand of God in the Great-Judgment Day and will then receive their just reward." So much, then, for the circular forwarded to us by Mr. Stokes himself. It appears that he is also distributing circulars to the public, and a correspondent has sent us one of these. In it Mr. Stokes makes the following statement: "A great many are losing their arm by amputation soon after being vaccinated, in many such cases the employers having to allow a pension for life." We have no hesitation in saying that this statement is, to put it politely, not true.

THE "WILLIAM MARTINDALE MEMORIAL."

AT a meeting of the former colleagues and friends of the late Mr. William Martindale, held at the Pharmaceutical Society on March 4th last, the following resolution was passed:—

> "With the view of perpetuating the memory of the late Mr. William Martindale, a past president of this society, it is desirable that steps be taken to procure a bust of our late deceased friend, to be placed in the house of this society, and in the event of the response being satisfactory, a medal or some other encouragement for the advancement of pharmacy be also provided, the exact nature of which shall be determined at a subsequent meeting of subscribers."

Subscriptions of any amount not exceeding two guineas are invited by the committee and should be addressed to the honorary secretary, Mr. G. S. Taylor, at 17, Bloomsbury-square, London, W.C. Postal orders and cheques should be made payable to the treasurer, Mr. Michael Carteighe, 180, New Bond-street, W., and crossed London and Westminster Bank, Westminster Branch.

◆

M.D.—The firm can have no monopoly of the appointment. If the post is publicly declared vacant any local medical man can apply for it. But it is not necessarily kind or wise to do a thing even when it is permissible. It would be better if the intending candidate consulted a prominent medical man in the locality.

Liverpool.—This was the subject of an address delivered at a meeting of the Wimbledon Medical Society on Nov. 8th, 1901. It was published in the *Clinical Journal* of Jan. 8th, 1902, and will reappear with Dr. Poore's Milroy Lectures shortly to be issued by Messrs. Longman.

C. J.—We think that the attention of the well-known medical man in question should be called to the fact that his name is being used to advertise diabetic beverages. But it is not necessary to do this publicly as there is no evidence that he is aware of the fact.

J. K.—We do not endorse our correspondent's view as to the limited knowledge of her particular condition exhibited by the medical profession. We recommend her to consult her medical attendant as to the scientific literature that she reads.

Subscriber.—We fear that our correspondent will have great difficulty in finding any appointment for which his previous experiences have fitted him. If he will more fully define his wants to us in a private letter we will endeavour to aid him.

Justice.—We shall have pleasure in replying in full if our correspondent will send us all the papers that he has with reference to the club—annual reports, balance-sheets, rules for admission of members, &c.

Senex, in writing on "Incontinence of Urine," has omitted to furnish us with his name and address.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.
